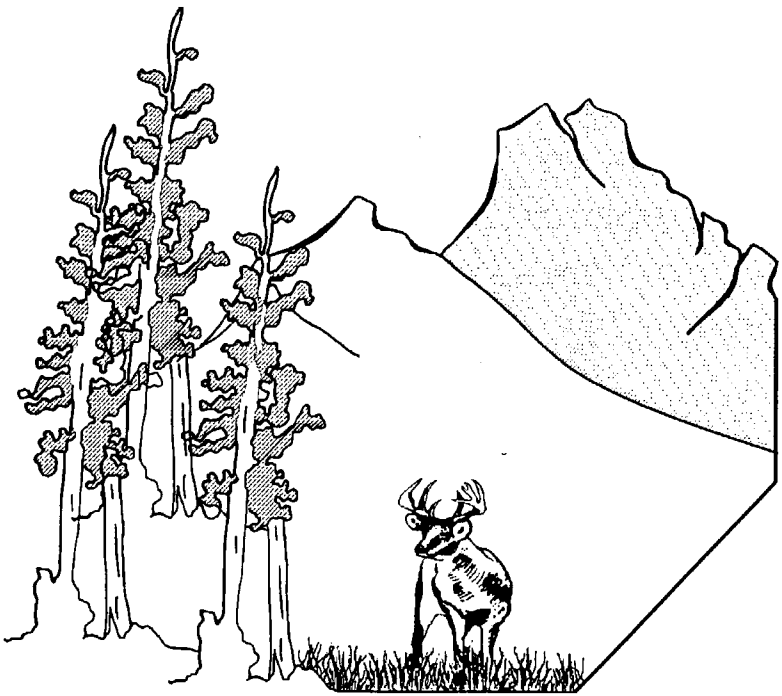
NATURAL HISTORY in the NATIONAL PARK SYSTEM and on the NATIONAL REGISTRY of NATURAL LANDMARKS

NATURAL RESOURCE REPORT
NPS/NR/NRTR-90/03



United States Department of the Interior•National Park Service

The National Park Service Natural Resource Report Series disseminates information on critical, current resource management issues that concern units of the National Park System.

Copies of this report are available from the following:

Natural History in the National Park System and on the National Registry of Natural Landmarks

Natural Resource Report
NPS NR NRTR-90 03

September 1990

National Park Service
USDI NPS
Washington, D.C.

TABLE OF CONTENTS

INTRODUCTION

This document has been prepared to identify what natural history themes are represented in units of the National Park System and in areas that have been designated National Natural Landmarks (NNLs). This publication updates "Part Two of the National Park System Plan - Natural History" published in 1972.

This update considers areas added to the National Park System since 1972 and includes a new section on NNLs organized by regions and themes to highlight representation of these resource types outside of the National Park System. This update is intended to be a companion to a similar publication addressing cultural resources entitled "History and Prehistory in the National Park System and the National Historic Landmarks Program."

The classification system for natural history used in this publication is essentially the same as the one used in 1972. Minor changes in theme subcategories were made to remain consistent with traditional ecological classification. The definition of themes is broad and allows only a general overview of natural feature representation within the parks and landmarks.

The information for this update was provided by the natural resources staffs in the National Park Service's (NPS) Washington Office, Regional Offices, and parks. As of September 1990, the National Park System included 356 units with more than 20 different designations such as national park, national monument, national recreation area, national battlefield, and national historic site. For this update, historic sites, battlefields, and similar areas less than 100 acres were generally excluded. However, in contrast to the 1972 publication, this update includes several parks that have important natural features regardless of size or "historic" designation.

This publication is not a strategy, plan, or proposal for expanding the National Park System. It provides a thematic framework for evaluating nominations for new parks and plans for managing parks already in the system. To be eligible for favorable consideration as an addition to the National Park System , a resource must meet established criteria for national significance, suitability, feasibility, and management alternatives. This publication is intended primarily to help answer the question of suitability by outlining what examples of a specific resource type are currently represented in the National Park System. This information also can help in planning for existing NPS units by identifying what other units have similar types of natural resources.

The NNLs program was established by the Secretary of the Interior to identify, recognize, and encourage the protection of sites containing the best remaining examples of ecological and geological components of the nation's natural heritage. Candidates for NNLs designation are identified primarily by natural history theme

studies conducted by qualified scientists. Landmarks are designated by the Secretary of the Interior based on nominations from the Director of the National Park Service.

The NNLs program relies on the voluntary cooperation of owners and managers of the sites listed on the National Registry of Natural Landmarks. These include resources on both public and private lands. In contrast to units of the National Park System that are established by Congress, status as an NNL does not change the ownership of a site, is not a land withdrawal, and does not authorize Federal acquisition or management of the site.

USING THIS PUBLICATION

This thematic framework is intended primarily to provide a basis for comparing potential new additions to the National Park System with other candidates and similar areas currently in the system. For example, if NPS were studying a site in northeast New Mexico, the following steps would be followed:

1. Check the map on page 5 to find what physiographic region the site falls within. For this sample, we will assume that the site lies within the Southern Rocky Mountains physiographic region.

2. Pages 47 and 48 list all of the natural history themes that characterize this region. The study of this site should identify which of those themes are present within the study area (some themes do not occur in every region).

3. For this sample, we also will assume that the site includes examples of a few themes under three major headings. Turning to page 47 of the thematic framework, we find the following park units listed under those themes:

SOUTHERN ROCKY MOUNTAINS

Landforms of the Present
Mountain Systems
Black Canyon of the Gunnison NM
Florissant Fossil Beds NM
Great Sand Dunes NM
Rocky Mountain National Park

*Works of Volcanism

Geologic History
Triassic-Cretaceous Periods
Curecanti NRA

Aquatic Ecosystems
Streams
Black Canyon of the Gunnison NM
Curecanti NRA
Great Sand Dunes NM
Rocky Mountain National Park

* Not represented

4. Turning to the section on the NNLs we find the following areas listed under the same themes on page 80.

SOUTHERN ROCKY MOUNTAINS

Landforms of the Present
*Mountain Systems

Works of Volcanism
Valles Caldera, NM

Geologic History
Triassic-Cretaceous Periods
Ghost Ranch, NM

Aquatic Ecosystems
* Streams

---

* Not represented

An analysis of the suitability of this area as a potential NPS unit would focus on the following questions:

Could the study area adequately represent the Works of Volcanism theme in this region since this is not currently represented in the National Park System?

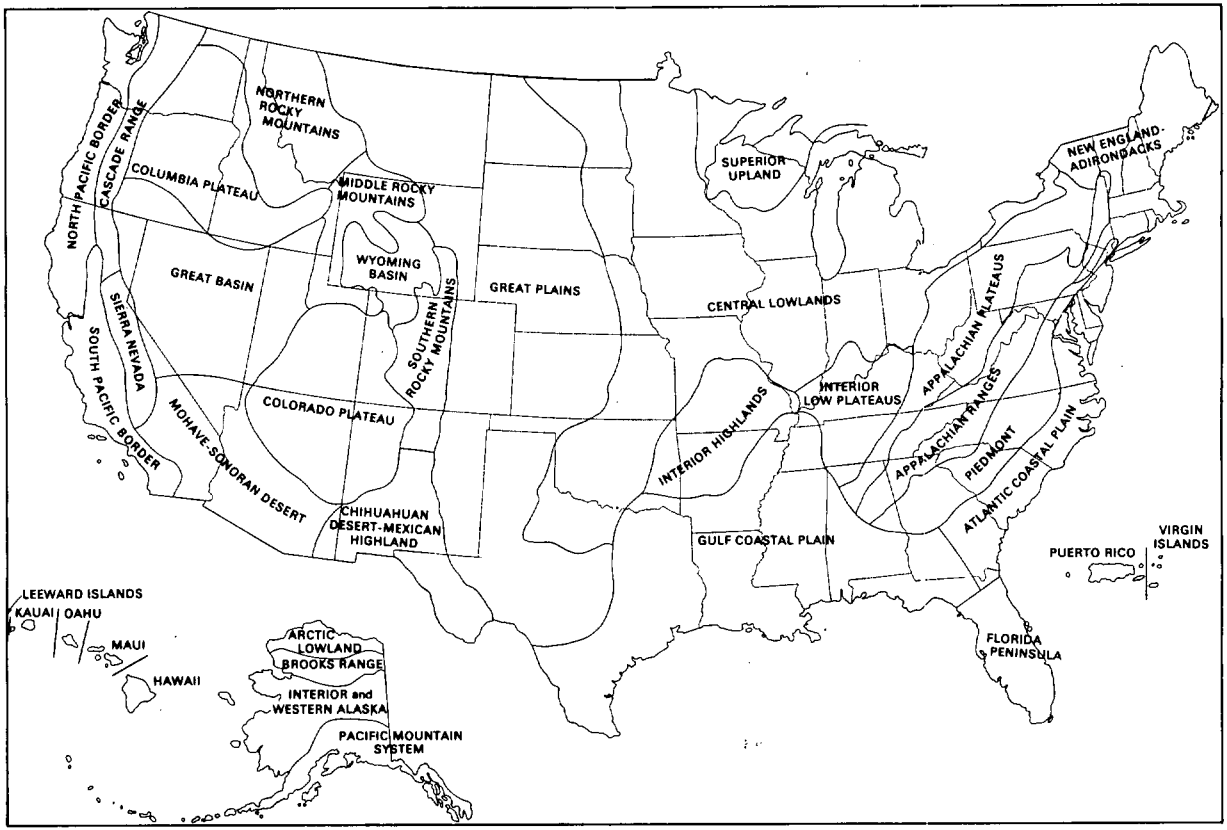
How does the study area compare with the one NNL designated under the Works of Volcanism theme in this region?

How do the other themes represented in the study area compare to similar resources in the park units listed under each theme? For example, do the mountains and streams in the study area include some unusual biological or other features that are very different from resources found in the four park units listed under those headings? Do these four parks encompass an adequate example of these features?

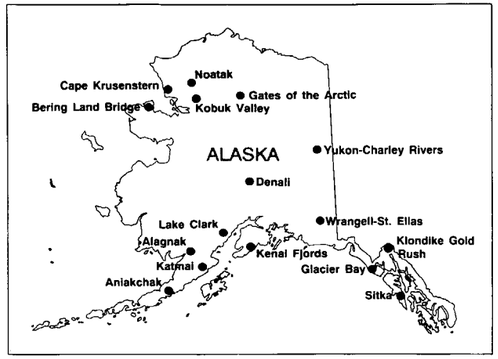
Are the parks listed as having an example of a theme managing their resources to focus on that theme? For example, although Curecanti NRA includes examples of Geologic History from the Triassic-Cretaceous period, protection and interpretation of this theme may not be a focus of attention in a unit managed primarily as a recreation area.

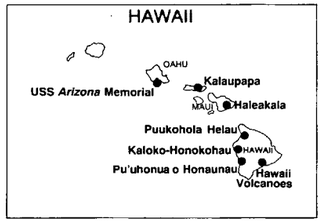
FIGURE 1. NATURAL REGIONS

*Based upon Fenneman's (1928) Physiographic Divisions of the United States.

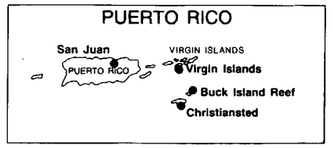


NATIONAL PARK SYSTEM

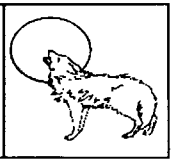




National Park of American Samoa is not shown on this map



NATURAL REGIONS DESCRIPTION



The following descriptions of natural regions are condensed from descriptions in "Part Two of the National Park System Plan: Natural History, 1972," with the exceptions of American Samoa and the Trust Territories, which are new. The Hawaiian Islands have been treated as one region, as have the Trust Territories.

Descriptions of natural history themes are those found in the above publication with the following few revisions. "Tundra" has been expanded to describe three subtypes. "Boreal forest" now includes subalpine forests of the Sierra-Cascade ranges. "Pacific forest" now excludes subalpine (boreal) forests of the Sierra-Cascade ranges, and "Deserts" now includes Great Basin Desert, to be consistent with traditional ecological classification and with regional discussion in the 1972 Plan.

North Pacific Border

This region includes the Olympic Mountains of Washington, the Coast Ranges of Oregon and northern California, and the Klamath Mountains of northern California and southern Oregon. Sand dunes border much of the coast in Oregon. Major rivers include the Columbia and large coastal streams. Lakes are a significant feature. Glacial sculpturing is particularly striking in the Olympic Mountains. Steep bluffs border most of the beaches. Luxuriant coniferous forest, including redwoods in southern Oregon and northern California, occupies the coastal region. Dry coniferous forest occurs at middle elevations in the Klamath Mountains and on the east slopes of the Coast Range in southern Oregon and northern California. Estuaries are extensive in this region. Offshore waters of the California Current are cold.

South Pacific Border

This region includes Coast Ranges, the Transverse Ranges, and the Peninsular Ranges of California. The Sacramento and San Joaquin rivers are the major surface water features. Steep cliffs and sandy beaches occur commonly along the coast. Dry coniferous forests on the mountains and chaparral, a product of the Mediterranean climate of coastal southern California, are the principal vegetation types. The cool California Current is warmer here than in Washington and Oregon.

Cascade Range

The Cascade Range, with its numerous volcanoes, extends from Washington to northern California. The Columbia River crosses the region from east to west. Lakes and streams are abundant in the heavily glaciated uplands. Boreal forest and some tundra cover the high elevations, with Pacific forest on the west slopes. Dry coniferous forests occur elsewhere at middle and lower elevations.

Sierra Nevada

The largely granitic Sierra Nevada stretches 400 miles south from the Cascade Range in central California. The steep east face of the range rises 11,000 feet above the Owens Valley. Mt. Whitney is the highest point at 14,495 feet. Glacial lakes, including Tahoe, are numerous. Alpine tundra, boreal forest, and dry coniferous forest are well represented. Pacific forest, with giant sequoia, occurs on the west slope, as does chaparral and oak woodland in the western foothills.

Columbia Plateau

The Columbia Plateau, consisting of broad lava plains and various mountain ranges, occupies eastern Washington, eastern Oregon, and southern Idaho. Deep gorges, such as those of the Snake River, have been cut into the plateau. Much of the region is arid and many lakes are saline. The Columbia, with its major tributary, the Snake, is the principal river system. Alpine tundra and boreal forest similar to that of the northern Rocky Mountains occur on the highest elevations. Dry coniferous forest is more extensive. Grassland, now greatly altered by cultivation and grazing, is the natural vegetation of most of eastern Washington, eastern Oregon and southern Idaho. Sagebrush desert occurs in much of eastern Washington, Oregon, and southern Idaho.

Great Basin

This region, which extends from parts of eastern California to eastern Utah, consists of numerous desert basins separated by mountain ranges. Many of these basins have an intermittent lakebed in its lowest portion. The Great Basin contains more than 160 isolated mountain ranges aligned roughly north-south. Permanent surface water is uncommon. Most of the permanent lakes are saline. At the lower elevations, low rainfall and cold winters have resulted in desert vegetation characterized by sagebrush and shadscale. Dry coniferous forest is extensive on lower slopes of mountains, and some boreal forest and isolated bits of tundra occur on the highest mountains.

Mohave-Sonoran Desert

The Mohave and Sonoran deserts occupy southeastern California, southernmost Nevada, and southern Arizona. Their physiographic features are roughly similar to those of the Great Basin. The major river system is the lower Colorado River. Both the Mohave and Sonoran deserts have hot summers and warm winters but their vegetation is different. The Mohave Desert of southern Nevada and southeastern California has simple plant communities dominated by creosotebush and bur-sage, with Joshua trees at 3000-4000 feet. The Sonoran Desert, mainly in Baja California and inland Mexico but extending into southern Arizona, has much more diverse vegetation characterized by columnar cacti.

Chihuahuan Desert - Mexican Highland

The main portion of this region is in Mexico but it extends into southern New Mexico and western Texas. The desert areas lie at 4000-6000 feet. Geologically diverse types of mountains rise above this base. Sand dunes are common. Surface water is uncommon. The Rio Grande is the major river. Ocotillo, creosotebush, mesquite, and numerous cactuses are among the most conspicuous plant species of the Chihuahuan Desert. Grassland and shrub savanna are widespread. On the mountains are chaparral at middle elevations and dry coniferous forest higher up. Isolated stands of boreal forest occur.

Colorado Plateau

This dry deeply-incised plateau covers parts of Utah, Arizona, New Mexico, and Colorado. Surface water is uncommon. The Colorado is the major river system. Rocks ranging in age from Precambrian through Eocene are exposed in the Plateau, most notably in the Grand Canyon. Much of the region is semi-arid to arid and has "cold desert" vegetation similar to that of the Great Basin. Grasslands once may have been common but most are now greatly disturbed and invaded by sagebrush. Dry coniferous forest is widespread, and boreal forest similar to that of the southern and middle Rocky Mountains occurs at higher elevations. Alpine tundra is found only on a few high mountains.

Northern Rocky Mountains

This section of the Rockies extends over western Montana, northeastern Idaho, and northeastern Washington. Some of its ranges exhibit spectacular glacial topography. Many of the headwaters of the Missouri and Columbia rivers rise here. Lakes and streams are abundant. Alpine tundra is fairly extensive because timberline is at 7000-8000 feet. Boreal forest, dominated by Engelmann spruce and subalpine fir, occurs at high altitudes. Dry coniferous forest occurs mainly in western Montana and much of Idaho. Pacific forest extends to northwestern Montana because of mild, moist Pacific air carried inland in a narrow corridor.

Middle Rocky Mountains

This region extends from southern Montana to northeastern Utah. Igneous activity in the region has been concentrated in the Yellowstone National park area, where the most outstanding hot water phenomena in the world occur. Spectacular canyons have been cut by the Green and Yampa Rivers. Most of the numerous lakes are of glacial origin. The Middle Rocky Mountains contain some of the prime areas of alpine vegetation in the United States. Boreal forest occupies the subalpine zone and dry coniferous forest the lower elevations.

Wyoming Basin

The topography of this region resembles that of the Great Plains. Dominated by large structural basins, the region also has several mountain ranges and much badland topography. The major streams and rivers typically rise in mountains adjacent to the Basin and flow more or less directly through it. The vegetation is a semidesert of sagebrush and grasses.

Southern Rocky Mountains

The Southern Rocky Mountains extend from southeastern Wyoming to north-central New Mexico, with most of the region in central Colorado. The headwaters of the Platte, Colorado, and Arkansas rivers are found here. Small alpine lakes, most of glacial origin, are scattered throughout the mountains. Alpine tundra covers large areas between 11,000 and 14,000 feet elevation. Boreal forest is extensive at high elevations and dry coniferous forest at low elevations.

Great Plains

Reaching from the Rio Grande of Texas north to Montana and North Dakota and to Great Bear Lake in Canada, the Great Plains region is largely plateau-like. The Black Hills rise 3000-4000 feet above the surrounding plains, and many other outlier mountain ranges occur in west-central Montana. The White River badlands of South Dakota and the Little Missouri badlands of North Dakota are outstanding examples of this topographic type. Large, low gradient rivers, fewer small permanent streams, and few lakes characterize this large area. Short-grass prairie is the most widespread vegetation type, with mixed-grass prairie in the eastern Great Plains. Boreal forest and dry coniferous forest occur in the Black Hills, juniper-oak savanna in central Texas.

Central Lowlands

This region covers a large part of the central United States, from north central Texas to eastern North Dakota and western Ohio. The extremely flat topography is largely the result of glacial drift which filled low places. Surface water ranges from intermittent small steams in prairie lands to the Great Lakes. Lakes occur mostly in the glaciated northern part of the region, and major rivers of the Mississippi system in the southern part. Various subdivisions of the eastern deciduous forest--beech-maple, maple-basswood, northern hardwoods, and oak-hickory--occupy much of the region, with tall-grass and mixed-grass prairies in the western portion.

Superior Upland

Repeatedly covered by advancing and retreating continental ice sheets during the Pleistocene epoch, this region is characterized by numerous lakes ranging in size from small ones to Lake Superior. It occupies northwestern Michigan, northern Wisconsin, and northeastern Minnesota. Precambrian rock of the Canadian shield underlies most of the region. Boreal forest and northern hardwoods are the principal vegetation types.

Interior Highlands

Stretching from southern Missouri to northwestern Arkansas and eastern Oklahoma, the Interior Highlands consist of the Ozark Plateau in the northern part and the Ouachita Mountains in the south, separated by the valley of the Arkansas River. Caverns and springs are abundant in the limestone plateaus of

southern Missouri. Oak-hickory forest is the dominant vegetation throughout this region.

Interior Low Plateaus

This region, mostly in western Kentucky and Tennessee, consists of a series of plateaus separated by prominent escarpments. The region is characterized by relatively large rivers and streams flowing generally northwest. Sinkholes and caverns are abundant in the extensive karst topography. The natural vegetation is western mesophytic forest, consisting of a mosaic ranging from mixed mesophytic forest to grassland.

Appalachian Plateaus

This long, narrow region between the Appalachian Ranges and the Interior Low Plateaus extends from New York to northern Alabama. The topography appears rolling, but major stream valleys are deeply incised. Lakes, including the Finger Lakes of New York, occur mainly in the glaciated northern part of this region. Rivers and streams are numerous and include headwaters of the Ohio, Delaware, and Susquehanna rivers. Mixed mesophytic forest, a very diverse subdivision of the eastern deciduous forest, occupies most of the region, with northern hardwoods in the northern section.

Appalachian Ranges

This region consists largely of the Blue Ridge Mountains and the ridge and valley physiographic province immediately to the west. The northernmost extension reaches into southern Vermont. Streams and rivers, usually small, are numerous. Lakes occur primarily in the glaciated northern portion. Caves are numerous, especially in the Great Valley of Virginia and the extreme southern part of the region. Boreal forest occurs at high elevations in West Virginia, Virginia, North Carolina, and Tennessee, and northern hardwoods in the northern end of the region. Oak forests are much more widespread.

Piedmont

The Piedmont region borders the Appalachian Ranges on the east, extending from southernmost Connecticut to south-central Alabama. This plateau is gently rolling with occasional monadnocks. The area is characterized by large, slow rivers and few natural lakes. Oak-pine forest, another subdivision of the eastern deciduous forest, occupies most of the Piedmont.

New England-Adirondacks

Four major mountain groups occur in this region: the Adirondacks, part of the Canadian Shield; and three groups that are part of the Appalachian chain--the Taconic Mountains, the Green Mountains; and the White Mountains. The entire region was glaciated and is well provided with lakes and streams. The coast is generally steep and rocky. The Continental Shelf north of Cape Cod is broad. The cold Labrador Current carries abundant nutrients. The estuaries of New England are narrow embayments with open access to the sea. Alpine tundra occurs on a few peaks of the Adirondacks, many in the White Mountains, and

on Maine's Mount Katahdin. Northern hardwoods are the dominant vegetation type, with boreal forest common at high elevations and in Maine. Oak forest dominates in southern New England.

Atlantic Coastal Plain

This region, averaging 75 to 100 miles in width, extends from Long Island to northernmost Florida. Topography is flat to rolling, with maximum elevations up to 800 feet at the western edge. The region is characterized by broad, slowly flowing rivers and streams. Large salt and fresh-water marshes adjoin the rivers. Swamps cover large areas. Beaches are characteristically broad and sandy. Long, narrow barrier islands are present off the coasts of North Carolina, Virginia, Maryland, New Jersey, and Long Island. The Sea Islands lie off the coast of Georgia and South Carolina. Offshore waters influenced by the Labrador Current are cool south to Cape Hatteras. South of Cape Hatteras, the warm subtropical waters of the Gulf Stream dominate. Mixed forests of oak, pine, beech, and other species dominate the uplands. Bald cypress, oak, and swamp black gum dominate swamps and river floodplains.

Gulf Coastal Plain

Wider than the Atlantic Coastal Plain, the Gulf Coastal Plain extends from northwestern Florida to southern Texas and up the Mississippi Valley to southeastern Missouri and adjacent Kentucky. The broad alluvial valley and delta of the Mississippi River are outstanding geological features. Many other large, low gradient rivers discharge into the Gulf of Mexico. Extensive marshes are present along the coastline of the whole region and inland in the Yazoo Basin. Broad, sandy beaches are characteristic of the Gulf Coast. Extensive barrier islands occur off the coast of Texas and the Florida Panhandle. Offshore waters are warm. Vegetation of the Gulf Coastal Plain varies with the geological substrate. Pine forests occupy large areas, and live oak forests are common near the coast. Various southern hardwood mixtures occur, with swamp forests of bald cypress and water tupelo along river floodplains, especially the Mississippi. Coastal prairie, similar to tall-grass prairie but more diverse, occupies much of coastal Texas and Louisiana.

Florida Peninsula

The Florida Peninsula is part of a platform of calcareous rocks which form the coastal plain and Continental Shelf at the southeastern corner of the United States. The emergent portion is a low plain. The southern tip is very low-lying and swampy. Water from Lake Okeechobee flows southward and westward for up to 100 miles before reaching the sea. Thousands of large and small solution-type lakes are found in north and central Florida. Swamps are extensive. Rivers and streams are of very low gradient. The beaches are sandy. Mangrove swamps, broad salt marshes, and coral reefs also occur along the coast. Karst features are prominent in north-central Florida. Southern mixed forest of beech, sweet gum, pine, and other species are dominant in northern Florida, with cypresses and hardwoods in swamps. Southern Florida is distinctly different, with subtropical pines, broadleaf evergreens, palms and

dry prairies on the drier sites. Sawgrass, wet prairie, freshwater swamp forest, mangroves, and salt marshes occur in wet areas. Offshore waters are warm.

Hawaiian Islands

The 1,600-mile-long Hawaiian Archipelago, of volcanic origin, consists of the islands of Hawaii, the Maui Island group, Oahu, Kauai and Niihau, and the Leeward Islands. In general, the volcanoes became extinct from northwest to southeast with the old and greatly eroded Leeward Islands the oldest, Mauna Loa and Kilauea the youngest, and the remaining volcanoes intermediate in age. Mauna Loa and Kilauea, on Hawaii, are still very active. Hawaii's Mauna Kea, 13,796 feet above sea level, is the highest peak in the Pacific. Spectacular deep gorges and sheer cliffs occur on several of the islands. Shorelines range from extensive sand beaches to sea cliffs. Coral reefs have developed along some shores, notably in the Leeward Islands and on the leeward side of East Molokai. Mountainous topography, varied substrates, and great elevational range combine to produce complex patterns of local climate and vegetation. Annual rainfall sometimes reaches 600 inches at high elevations on Kauai, whereas leeward sides of mountains may be quite dry. Temperatures range from near tropical at sea level to alpine above tree line. Although much of the original vegetation has been altered or destroyed, samples persist, including lowland rain forest, dryland sclerophyllous forest, montane rain forest, and high-altitude tussock grassland and microphyllous scrub. Endemism is very high though less among marine species than terrestrial species. On land there are great differences in biota from island to island.

Pacific Mountain System

This region consists mainly of a broad belt of ranges paralleling the southern coast of Alaska. These ranges include the coast range of southeast Alaska; the St. Elias Range, with elevations to 18,008 feet; the Chugach-Kenai Mountains; the Wrangell Range, with elevations to 16,523 feet; the Talkeetna Mountains; the Alaska Range, including 20,320-foot Denali, highest peak in North America; and the Aleutian Range, extending 1,600 miles from west of Anchorage to the western tip of the Aleutian Island chain. About 80 major volcanoes, many still active, are contained in the Aleutian Range. Nearly all the high ranges were covered and sculpted by glaciers during the Pleistocene Epoch, and 20,000 square miles of glaciers remain in Alaska. The Pacific Mountain System contains an enormous number of lakes and streams. The rugged coastline of Southeast Alaska is cut by channels, straits, and fjords; the Alexander Archipelago contains many islands of various sizes. The Kodiak Island-Gulf of Alaska area and the Aleutian Islands have a rocky, steep coastline. Treeless areas consist of glaciers, permanent snow fields, gravel and rock, barren volcanic peaks and recent lava flows, as well as dry and moist tundra. Boreal forest composed of white spruce and other species is generally restricted to the two plains regions--the Copper River plateau and Cook Inlet-Susitna lowlands--and along low-lying stream courses. Pacific forest, with sitka spruce, western hemlock, and other species, occurs along the coast to the Kenai Peninsula.

Interior and Western Alaska

This is a region of diverse topography drained primarily by the Yukon and Kuskokwin rivers, the largest in Alaska. An irregular assemblage of intricately dissected upland and broad alluvium-covered lowlands characterizes the topography. Discontinuous groups of mountains occur on the rolling upland. Water types range from large, clear, glacially formed lakes to brown sphagnum bog ponds, and from clear, torrential mountain streams to huge, slow-moving, silt-laden rivers. Surface water is a dominant feature in many portions of the region. Rainfall is low, but evaporation is also low and surface water does not percolate because of permafrost. Pleistocene glaciation was of quite limited extent, occurring locally over the highlands. Much of Alaska's west coast is bordered by coastal lowland, including the vast, marshy Yukon-Kuskokwim delta. Interior Alaska vegetation is a huge mosaic of forest, muskeg, and tundra. Small and large patches of dry and wet tundra occur. Boreal forest generally occupies the lower elevations up to 2,000-3000 feet in the interior, and 200-800 feet in western Alaska. White spruce is the dominant species on better drained sites, black spruce on poorly drained soils.

Brooks Range

The Brooks Range includes a group of mountain masses extending from the Canadian border across most of Alaska. Several large glacial lakes lie in mountain valleys formed by ancient glaciers and dammed by morainic debris. The Range separates waters flowing northward into the Arctic Ocean from those flowing southward into the Yukon River tributaries and westward into Kotzebue Sound. The Noatak River, the only major river lying entirely in the Brooks Range, bisects the range at the western end. There is considerable evidence of Pleistocene glaciation, though it was not as extensive as in the southern Alaska ranges. The vegetation is primarily dry tundra above 2,500 feet and moist tundra on poorly drained sites below 2,500 feet. Limited areas of boreal forest dominated by white spruce occur along river courses at low elevations on the southern slope of the Brooks Range.

Arctic Lowland

The Arctic Lowland, or Arctic Slope, 100-200 miles wide, stretches across northern Alaska. Two distinct parts are evident--the southern Foothills Belt and northern Coastal Plain. While the Foothills Belt has very irregular topography, the Coastal Plain is very flat and nearly half of it is covered with water. Northward flowing rivers originating in the Brooks Range or foothills meander over wide flood plains. The region is marked by thousands of lakes and low, wet areas. The arctic shoreline nearly everywhere has earth banks 3 to 30 feet high behind narrow pebble beaches. Underlain by permafrost, the Arctic Lowland is a vast treeless plain. Moist tundra predominates in the Foothills Belt and wet sedge tundra on the Coastal Plain.

Virgin Islands

The U.S. Virgin Islands, a part of the Lesser Antilles Leeward Islands, include 50 islands and cays of which St. Croix, St. Thomas, and St. John are of significant size. St. Thomas and St. John are generally mountainous and made up mostly of volcanic rocks, whereas St. Croix has three major landforms--the Northeast Range, the East Range, and an intervening coastal plain. Shorelines vary, including rocky, coral bank, coral beach, boulder or gravel beach, sand beach, and mangrove swamp. Considerable reef development has occurred around St. John, at the eastern end of St. Thomas, around the eastern two-thirds of St. Croix, and at Buck Island. The major vegetation types, now much disturbed, are moist forest, dry forest, dry forest with cactus, cactus woodland, wind-flattened scrub, mangrove, beach vegetation, and Croton-acacia scrub.

Puerto Rico

Puerto Rico, 110 miles long and 35 miles wide, is the smallest and most easterly of the Greater Antilles. Mountainous topography reaching elevations of 2,000 to 4,000 feet runs the length of the island. Foothills and coastal lowlands comprise the regions north and south of the mountains. Several continuously flowing streams drain the rainy windward portion of Puerto Rico. On the dry leeward slopes, intermittent steams predominate. Mountain streams are swift-flowing, lowland streams are slow moving and have broad flood plains. The east and west coasts are characterized by palm-fringed beaches strung between headlands and marine cliffs. Much of the north coast has 200-foot marine cliffs and protective beaches. Most of the south coast is gently sloping. Extensive karst topography occurs in the limestone regions. Vegetation zones include the littoral zone, lowland rain forest, seasonal evergreen forest, hill scrub, semi-deciduous forest, montane forest, montane scrub, and elfin forest. Along the coast, saltwater ponds, lagoons, and shallows support algal meadows and turtle grass beds. Reef complexes support marine algal crusts, kelp beds, and mangroves. Mangroves form a broken ring around the island.

Guam

The largest (212 square miles) and most southerly of the Mariana Islands, Guam lies in the western Pacific Ocean 1,200 miles east of the Philippines, well within the tropical zone. The northern half of Guam is a broad, gently tilting limestone plateau bordered by steep cliffs. The southern half is primarily a dissected volcanic upland. Permanent streams occur only in the southern half of Guam. The island has three basic types of shoreline: coral limestone, low swampy coast, and sandy beach. Significant vegetation types are forest of elevated hard limestones, ravine forest of southern Guam, marshes and swamps, strand vegetation, grassland or savanna vegetation, and vegetation of the argillaceous limestone area.

American Samoa

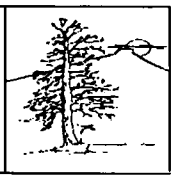
American Samoa, with a total land area of 76 square miles, includes the inhabited islands of Tutuila, Tau, Olosega, Ofu, and Aunuu and two uninhabited coral atolls named Rose Island. Swains Island, not a part of the Archipelago, is

also a part of American Samoa. Except for the coral atolls the islands are rocky and were formed by volcanic activity within the past 7 million years. Tutuila, the largest island, rises to an elevation of 2,142 feet. Rainfall is 100 to 300 inches; temperatures average 78-80°F for all months. Lowland and montane rain forest are the principal natural vegetation types.

The Trust Territories

This region consists of the Mariana, Marshall, and Caroline Islands, located in the southwest Pacific. These island groups consist of more than 2,000 islands, with a total land area of about 700 square miles. Three basic types of islands occur here: low coral atolls, high islands of volcanic origin, and islands that represent a combination of coral limestone and volcanic uplift. The highest elevation, 3,166 feet, occurs on Agrihan, in the northern Marianas. The climate is warm and humid, with temperatures usually ranging between 75°F and 85°F. Rainfall on larger volcanic islands may reach 300 to 400 inches a year, but on atolls in the northern Marshalls, annual rainfall may be as low as 20 to 30 inches, with prolonged periods of drought. Natural vegetation is limited on coral atolls, but dense rain forest grows in the interior of high volcanic islands. In the northern Marianas, areas resembling savanna, intermixed with dense forests, occur.

NATURAL HISTORY THEMES



In identifying themes, two major interrelated categories of natural phenomena must be recognized. One, the geological category, comprises phenomena that result from forces and processes acting through and upon the earth's inorganic substance to produce landforms and other evidences of nonliving entities. The biological world is here represented as fossilized records of organisms but the fossils and the processes through which they are preserved are geologic. Themes within the geological category must take into account the historical aspects of the development of the earth's surface and the evolution of life. In this respect, the geological time scale, recognized and generally accepted by geologists, provides a useful and workable tool. Individual themes must embrace segments of time of sufficient duration to include closely related events and associated land structures, environments, and stratigraphic formations, including fossiliferous deposits. Certain existing landforms and landscape features are of such prominence and importance as to require recognition and study under special themes outside of the historical context.

The second major category covers biological forms and processes. Since the foci of interest and importance lie in the interactions among the biological components and the abiotic environments, as well as in the individual life forms, this is more properly designated as the ecological category.

Within the ecological category, themes are based primarily on the ecosystem, which is defined as the natural community including its component organisms together with the abiotic environment, all forming an interacting system. As in the geological category, there are some biological phenomena that have intrinsic interest apart from the ecosystem in which they occur.

The basic philosophy of a system of themes has implications and connotations that require explanation. Natural history is complex. To individual scientists, as to individual laymen, it may have very different meanings. These differences arise from the consideration of these entities and processes from various points of view. Collectively among human minds, natural history, therefore, becomes polydimensional and difficult to resolve into a generally acceptable rational system of categories of a nature that would be useful for purposes of evaluation and selection of representative areas. The only apparently reasonable alternative is a system of themes such as outlined below. These themes involve not only entities and processes but also the aspects from which they are viewed. By their very nature, themes intersect and overlap. Because of this, no single area is characterized solely by a single theme, although a single theme may be of overwhelmingly dominant importance.

GROUP I. LANDFORMS OF THE PRESENT

Landforms of the present include the principal features of the existing natural landscapes. Each landform possesses certain distinguishing qualities and characteristics which set it apart from the others. Moreover, each is a manifestation of geologic events and processes that have determined its size, shape, composition, and structure. The qualities and characteristics of landforms, therefore, possess a dual significance. This theme describes the character of the landscape as a physical and scenic entity as it exists today, and present and past geologic events and processes.

Each of the themes embraces landforms with common major qualities and characteristics. The geologic events and processes which created the landforms within each theme are usually similar in some respects, but this is not always true. For example, plains are always level - or nearly level - areas of some considerable extent, but the underlying rocks may vary greatly in composition and structure.

Theme 1. Plains, plateaus, and mesas

Plains, plateaus, and mesas are characterized by their level, or nearly level, surface. Plateaus and mesas are essentially segments of plains standing at some considerable elevation above the surrounding country. Plateaus may vary from the norm, however, in that their surfaces may be highly dissected by erosion or form the bases of mountains rising to still higher elevations.

Theme 2. Cuestas and hogbacks

Cuestas are asymmetric ridges possessing a tilted dip-slope surface on one side, which is held up by a rock stratum relatively resistant to erosion, and possessing a steeper erosion scarp on the other side cut across the strata. Depending on the amount of cross drainage, their crest may be straight or scalloped. Cuestas are especially characteristic of the semi-arid West, and may form the foothills of higher mountains. Hogbacks are sharp-crested ridges formed on the more resistant rocks where the rock dips are steeper than those prevailing in cuestas.

Theme 3. Mountain systems

Although mountains may represent various types--folded, fault block, dome, or volcanic--all of them are eminences standing either alone or as part of a range or group. Mountains stand conspicuously above the surrounding country, as a rule, and are characterized by relatively small summit areas and frequently by a considerable extent of bare rock surface. Their form, composition, and structure are manifestations of a wide variety of geologic events and processes and constitute veritable record books of the Earth's history. Particularly worthy of attention are the folded structures visible in some areas of bare rock exposure.

Theme 4. Works of volcanism

All landforms of the present representing the works of volcanism have been created by the movement and the intrusion or the extrusion of molten masses of

rock called magma which subsequently cooled and solidified. Even today, in some places, this magma reaches the surface in a molten condition and is extruded explosively to leave a crater or as extensive lava flows prior to solidification. Cone volcanoes, lava flows, and ash necks become prominent land features chiefly where they remain as walls and pinnacles following erosion of the invaded country rock. The surfaces of lava flows in many places have assumed bizarre shapes owing to flowage of lava after the surface is partly cooled, and intricate caverns develop below the surface. Lava flows, sills, and dikes commonly break into hexagonal columns perpendicular to the cooling surface, and these columns may produce striking erosion features. Calderas are large circular basins associated with volcanic activity, and were produced either by erosion blowouts, or as subsidence basins.

Theme 5. Hot water phenomena

Hot water phenomena such as geysers, hot springs, fumaroles, bubbling paintpots, hydrothermally altered or colored terrain, and siliceous sinter terraces are closely related in that they require water and sources of heat. As a rule, such features are found in areas still subject to volcanism or where volcanism has occurred in the comparatively recent geologic past.

Theme 6. Sculpture of the land

This theme includes landforms produced by erosive action of water and wind, landslides, and other physical or chemical landshaping events or phenomena. Features resulting from the sculpture of the land by these processes commonly appear as "landforms superimposed upon landforms" such as occur when a stream valley or badlands topography is developed on a plateau or a mesa, or within a mountain system. Bare rock canyons, buttes, and rock needles are carved out of the bedrock. Pedestal or toadstool rocks usually have a hard cap rock which has protected weaker underlying strata from erosion.

Theme 7. Eolian landforms

Sand dunes oriented both perpendicular and parallel to directions of major wind movement are prominent topographic features in places. Their shapes are determined in part by the influence of vegetation. The composing material may be quartz, calcareous, or gypsum sand.

Theme 8. River systems and lakes

River systems and lakes are noteworthy features of the natural landscapes of which they are a part. Many rivers, not yet at grade, are characterized by waterfalls over the harder rock ledges. Others have reached grade and now meander in alluvial valleys. Some meandering rivers have been rejuvenated to produce incised meanders which may have vertical canyon walls.

Lakes bear a close relationship to the steams flowing into them which makes it practicable to include both rive systems and lakes within the same theme. River systems and lakes are usually within or superimposed upon other landforms as in Sequoia and Kings Canyon National Parks. Here the upper reaches of river

systems and a number of lakes lie within and upon the Sierra Nevada which is itself an outstanding example of a fault-block mountain system. The valley sides of both rivers and lakes commonly reveal evidences of earlier geologic history in the form of terraces.

Theme 9. Works of glaciers

The works of glaciers include landforms produced by both mountain and continental glaciers. Among these forms or features are cirques, aretes, tarns, hanging valleys, canyons with U-shaped transverse profiles, moraines, drumlins, eskers, and kames. The glaciers and their associated features on the Mount Rainier cone volcano are classic examples of this superimposed relationship. Glacial striae in thoroughly scoured areas are prominent features in many areas.

Theme 10. Seashores, lakeshores, and islands

Along seashores and lakeshores, landforms occur which are peculiar to these environments and which have been produced by natural processes at work within them. Eroded cliffs, stacks, beaches, dunes, barrier beaches, sandbars, hooks, and sandpits are examples of landforms in this category. Closely related features are the offshore islands of many regions; these show transitions to more remote islands of other regions. Other landforms, of themselves worthy of recognition, are normally superposed on islands.

Theme 11. Coral islands, reefs, and atolls

Coral islands, fringing reefs, barrier reefs, and atolls are landforms produced by the work of living organisms acting in concert with other processes. These landforms are always interesting and possess outstanding scientific value and beauty. The largest thing built by living organisms is not the Great Wall of China or the great power and irrigation projects of today, but, rather, the enormous barrier reef fringing Australia's northeastern coast constructed by corals and algae.

Theme 12. Caves and springs

Caves are subterranean features, most of which have been formed by solution of limestone or dolomite, though deposition of calcareous materials has alternated, in many instances with solution, and may have been the most recent event. Many caves are associated with underground streams. Locally, the rock cover over parts of such streams has been dissolved or otherwise eroded so that the stream is subaerial in parts of its course, underground in other parts. The open valley parts of such "blind rivers" or "lost rivers" are fascinating elements of the local landscape. In a more advanced stage of erosion, natural bridges may be formed. Many large steams that have flowed underground for considerable distances reappear at the surface as spectacular springs.

GROUP II. GEOLOGIC HISTORY

The records of the geologic history of the earth are found in the rocks. These records may be read from the composition, structure, and relationships of rocks and the fossils they contain. Earth history embraces a period of billions of years. The development of the themes involves the location, identification, and evaluation of the more significant geologic records in terms of their value, usefulness, and suitability in illustrating the history of the Earth and its life.

Theme 13. Precambrian era

This theme embraces the entire span of the Precambrian Era between about 3 billion and 600 million years ago. This time interval is characterized as The Morning of Life for within it the first life--- algae, fungi, and soft-bodied marine plants and animals--developed on the earth. The distribution of Precambrian rocks is worldwide, but in the United States rocks of this age are found in the Cordilleran region and the Appalachian Mountains. They also occur in the Lake Superior region and in a few localities of the southern midcontinent west of the Mississippi River.

Theme 14. Cambrian - Early Silurian periods

The Cambrian, Ordovician, and Early Silurian periods--a time span between about 600 and 420 million years ago--was the age of primitive invertebrates. Life forms were restricted to the water and were, in time, dominated by shellfish of a bewildering variety. Trilobites, brachiopods, sponges, and corals thrived, and jawless fish representing the first vertebrates made their appearance.

Theme 15. Late Silurian - Devonian periods

The Late Silurian and Devonian periods--a time span between about 420 and 350 million years ago--embraced the rise of vertebrates and the first forest. Life forms continued to exist primarily in the water, but terrestrial life began with the first land plants. During Devonian time, plant growth attained tree size; also primitive, land-living creatures became more firmly established and amphibians evolved.

Theme 16. Mississippian - Permian periods

The Mississippian, Pennsylvanian, and Permian periods include a span approximately between 350 and 220 million years ago. Crinoids attained their culmination; ammonoids and their successors, the ammonites, developed; the earliest reptiles appeared, and fish, including over 200 species of sharks, flourished. Trilobites became extinct but coal-swamp forests supporting a wide variety of insects prevailed.

Theme 17. Triassic - Cretaceous periods

Triassic, Jurassic, and Cretaceous periods, a time interval between some 220 and 70 million years ago, has been called the age of reptiles. This span embraces the dominance and extinction of dinosaurs and the flourishing of sea

going and flying reptiles. Modern plant types were on the rise during the latter part of this time interval.

Theme 18. Paleocene - Eocene epochs

The Paleocene and Eocene epochs-- between some 70 and 40 million years ago--embraced the time of the emerging dominance of mammals. Mammals, most of them different from those of today, filled niches which had been vacated by the extinct mammal-like reptiles, dinosaurs, and pterodactyls. Modern marine animals and fresh water fishes were on the rise.

Theme 19. Oligocene - Recent epochs

The Oligocene, Miocene, Pliocene, Pleistocene, and Recent epochs-- beginning about 40 million years ago and extending to the present time-- has been called the "Golden Age of Mammals". During this period modern life forms became well established. The age of prehistoric camels, horses, and dozens of other mammals, descendants of which are common today, are included. This is also the time (Pleistocene) of the remarkable large mammals of the ice age, and the development of humans and their civilizations, as well as all modern life forms.

GROUP III. LAND ECOSYSTEMS

There are literally thousands of kinds of land-dwelling plants and animals, and the number of associations among them are numerous. For purposes of a survey of natural areas, characteristic groupings of some of the more common and conspicuous forms are referred to as communities in the themes below.

Since the kind of community is intimately related to a kind of environment, it is necessary to look upon a group of organisms plus their environment as constituting a basic unit, and such a unit is commonly referred to by biologists as an ecosystem. The vegetative components of natural communities are generally more conspicuous than are the animal members and are more stable with respect to location and population density. Therefore, the name designations of land ecosystems stem from the types of vegetation which characterize them, but the animal populations and sometimes physical environmental features are often important elements in identifying and evaluating sites, as well as in shaping them.

Theme 20. Tundra

Tundra exists in a broad plain across the northernmost reaches of North America, with restricted occurrence on high mountains farther south. Tundra is a treeless area on which the principal vegetation consists of grasses, sedges, perennial herbs, and dwarf shrubs. Terrain is often poorly drained and climate alternates between a continuously cold, long harsh winter and a very short, cool to cold summer. Arctic tundra often is underlain by permanently frozen ground called permafrost. Associated with the permafrost are such tundra peculiarities as solifluction (a flowing of soil downslope), soil polygons, and frost boils. Alaskan tundra may be subdivided into three broad types: wet meadow tundra, shrub/tussock tundra, and alpine tundra. Wet meadow tundra, composed

largely of grasses, sedges, forbs, mosses, and lichens, occurs chiefly in wet areas of the coastal plains. Shrub/tussock tundra, characterized by tussock cotton-grass and ericaceous shrubs, occurs primarily in the piedmont and drier areas of the coastal plains. Alpine tundra, with a diversity of species and much bare ground, occurs at high elevations. Characteristic animals of Alaskan tundra are arctic fox, arctic hare, caribou, and lemming.

Alpine tundra also is found farther south in the Rocky Mountains, Sierra-Cascade ranges, and northern parts of the Appalachian chain. Here, many species of plants are closely related to the arctic tundra species but the mammals characteristic of arctic tundra are lacking. Among the common mammals are hoary marmot, bighorn sheep, and pika.

Theme 21. Boreal forest

Just south of the tundra is a belt of forest stretching from western Alaska eastward to the Atlantic coast in Labrador, Newfoundland, and Nova Scotia. Two principal trees characterize this forest: white spruce and paper birch. In the eastern half, balsam fir and jack pine are also characteristic. There is an extension of the northern forest southward along the Appalachian highlands to North Carolina and Tennessee. Here, white spruce is replaced by red spruce, paper birch is replaced by yellow birch and, in North Carolina and Tennessee, balsam fir is replaced by the closely related Fraser fir. White spruce and red spruce overlap in northern New England and the Maritime Provinces.

A corresponding southward extension along the Rockies is characterized by sub-alpine fir and Engelmann spruce, and another extension in the Cascades and Sierra Nevada is typified by red and silver fir.

The climate of the boreal forest is scarcely less severe than the tundra, but summers are longer, and precipitation somewhat greater. Paper birch, aspen, jack pine, lodgepole pine, red pine, and white pine are very common successional species in the boreal forest, and may last many years as distinct communities of utmost beauty and value. Among the animals, woodland caribou, moose, snowshoe hare, gray wolf, red fox, red squirrel, marten, wolverine, lynx, and several species of grouse and thrush are common.

Theme 22. Pacific forest

Bordering the Pacific Ocean from Alaska to northern California is a region of mild temperatures and moderate to heavy precipitation. The region extends from the coast inland to include (with the exception of the Central Valley and southern fifth of California) the seaward slopes of the Cascade and Sierra Nevada ranges. The essentially mountainous terrain of much of this region produces altitudinal zones that vary in climate and in the resulting plant and animal life. On the highest peaks there are perpetual fields of ice and snow; below the tundra are boreal forests of this theme, consisting of such species as white fir, giant sequoia, Douglas-fir, and sugar pine. The forests at low altitudes along the coast consist mainly of coniferous trees such as western arborvitae,

Douglas-fir, western hemlock, redwood, and Sitka spruce. Northward from the Olympic Peninsula, hemlock and Sitka spruce dominate. Southward from the Olympic Peninsula, Douglas-fir and redwood become increasingly dominant.

Animals common in this community include black bear, mule deer, coyote, cougar, raccoon, mountain beaver, golden-mantled ground squirrel, chickaree, and several species of chipmunks.

Theme 23. Dry coniferous forest

On the lower slopes of the Rocky Mountains and the eastern slopes of the Cascade-Sierra system there occur belts of coniferous forest and woodland dominated by Douglas-fir, ponderosa pine, and pinyon-juniper. The climate here is warmer but drier than that of the boreal (or subalpine) forest above, with drought setting the lower limits of elevation where these dry forests give way to steppe or chaparral. Deer, black bear, porcupine, coyote, chipmunks, magpie, Steller's jay, and pigmy nuthatch are common animals.

Theme 24. Eastern deciduous forest

From a central area in the southern Appalachian highlands, mainly winter-deciduous tree species spread in all directions--northward to the Great Lakes area, westward through the first tier of states west of the Mississippi River, southward to the Gulf of Mexico, and eastward to the Atlantic Coast. Oaks, hickories, maples, buckeye, basswood, tuliptree, hemlock, beech, and other hardwood species combine in various ways to form several distinctive groupings: oak forest, beech-maple forest, northern hardwoods, mixed mesophytic forest, and southern mixed forest. Extensive pine forests mark areas in the Southeast where frequent burning prevents the growth of broad-leaved trees and maintains more desirable timber, forage, and game.

Climate in this region is characterized by moderate-to-cold winters and hot summers. Precipitation varies from about 30 to over 50 inches annually. The most northern portions may have continuous snow cover throughout the winter, but snow is rare in the southern portion. White-tailed deer, raccoon, fox, thrushes, warblers, and the copperhead snake are common animals. Formerly, bison, cougar, and gray wolf ranged through much of the area.

Theme 25. Grassland (steppe)

Grassland is the most extensive formation in North America, extending westward from the edge of the eastern deciduous forests and covering the lowlands about the foothills of the Rocky Mountains to the Sierra-Cascades and from southern Saskatchewan and British Columbia to southern Texas. Throughout the formation, the rainfall is so low that the soil regularly dries out and the grasses become dormant each year. Total annual precipitation ranges from between 30 and 40 inches in the east to about 7 inches just east of the Cascades. In the north, winters are long and very cold but, in the south, winter temperatures seldom drop much below freezing.

Because there are large differences of climate within the grassland formation, there are corresponding differences in the vegetation. Along the eastern border of the formation, where precipitation is greatest, "tall-grass prairie" is the major vegetation type. Some of the dominant grasses are Stipa spartea, Bouteloua gracilis, B. curtipendula, Andropogon scoparius, A. gerardi, Panicum virgatum and Sorghastrum nutans. Composites and legumes are especially conspicuous among the broad-leaved herbs. Tall-grass prairie also dominates many sites formerly subject to regular burning in Illinois, Wisconsin, Minnesota, and Missouri, the combination of these sites often being referred to as the "prairie peninsula."

In the western portions of the central plains, where precipitation is lower, are the "short-grass plains." Bouteloua gracilis and Buchloe are the major dominants in this area of short grasses.

Between the Rockies and the Cascade-Sierra system, rainfall is mainly restricted to winter, rather than being concentrated in summer, as east of the Rockies, and the character of the steppe is correspondingly different. Characteristic grasses are Agropyron spicatum, Festuca idahoensis, and Oryzopsis hymenoides, and over most of the area there is a conspicuous overstory of shrubs, especially sagebrush or shadscale. Much of the interior valley of California originally supported grassland in which Stipa pulchra was the leading dominant.

Bison, pronghorn, elk, coyote, wolf, jackrabbit, kit fox, badger, ground squirrels, prairie dog, pocket gopher, prairie chicken, sage hen, and black-footed ferret are characteristic of grassland, but bison and elk are essentially restricted to the area of summer rainfall.

Theme 26. Chaparral

The dominant plants of chaparral are broad-leafed, mainly evergreen, species of shrubs or low trees, occurring as a dense scrub or woodland or in scattered arrangement with grass interspersed.

Two subdivisions may be made:
(1) Woodland---evergreen forest trees including several oaks, tanbark-oak, California-bay, madrone, chinquapin, and wax-myrtle. (2) Scrub---shrubs of many genera and species, the most important of which are manzanita, chamise, buckbrush, scrub oak, and mountain-mahogany.

Theme 27. Deserts

Deserts range from areas with no vegetation to areas with sparse, shrubby vegetation. Throughout the deserts, variations in soil texture, drainage, and salinity produce distinctive variations in vegetation.

The North American desert is traditionally divided into four geographic sub-regions: Great Basin Desert, Mohave Desert, Sonoran Desert, and Chihuahuan

Desert. Sagebrush characterizes the Great Basin Desert, which has cold winters and warm summers. One common, simple community-type consisting mainly of an open stand of creosotebush occurs throughout the other three deserts, which have warm winters and hot summers.

The Great Basin Desert occurs in much of the lower elevations between the Rocky Mountains and the Sierra Nevada-Cascade ranges. Perennial grasses are an important component in the northern part of this desert.

The Mohave Desert occupies much of inland southern California and adjacent Nevada and northwestern Arizona. Joshua-tree is the outstanding characteristic plant.

The Sonoran Desert extends from southeastern California to the western edge of New Mexico. The species that characterize the Sonoran Desert are ocotillo and the cactuses, especially the saguaro, organpipe, and other conspicuous columnar species.

The Chihuahuan Desert of eastern New Mexico and southwestern Texas is characterized by mesquite, ocotillo, yucca, agave, sotol, and nolina.

Typical animals of the North American deserts include coyote, javelina, bobcat, bighorn, jackrabbit, pocket gopher, kangaroo rat, packrat, antelope ground squirrel, ring-tailed cat, rattlesnake, road-runner, raven, and numerous lizards.

Theme 28. Tropical ecosystems

Tropical areas are limited in the United States and possessions to Hawaii, American Samoa, and other Pacific islands; Puerto Rico and the U.S. Virgin Islands; and the southern tip of Florida, including the Florida Keys. Astronomically speaking, the "tropics" occur in that area bounded by the Tropics of Cancer and Capricorn; but oceanic influences on southern Florida result in a vegetation that is outstandingly tropical in its character despite its extra-tropical position. Due to the geographic dispersion of tropical lands belonging to the United States, the vegetation is highly differentiated, so this theme is complex in its constituent parts.

Seasonal variation in the tropics is minimized by the fact that day length varies but little from 12 hours during all seasons, eliminating the long-winter-night, long-summer-day regime of temperate areas. On the other hand, wind patterns, continental position, and mountain ranges giving rise to rain-shadow phenomena do create seasonally wet-and-dry areas in the tropics as well as in temperate regions. Altitudinal variations also create vast differences in climate, vegetation, and attendant animal life.

Tropical formations of major importance are:

A. Lowland rain forest--temperature more or less constant and warm with any tendency toward drought offset by a coincident season of lower temperature.

B. Summer-deciduous forest--a forest with wet and dry periods alternating each year, and the trees, or many of them, leafless during the dry season.

C. Woodland and scrub formation--found in areas of still more pronounced drought, with small-leaved shrubs and low trees among which legumes are conspicuous.

D. Swamp and mangrove formations--forest or scrub growing where saline or fresh water covers the soil during at least part of the year.

E. Savanna--grassland, usually with scattered trees, related to abnormal soil conditions or recurrent burning of summer-deciduous forest.

F. Montane rain forest--evergreen forest of the cool, misty upper slopes of mountains, extending to upper tree line.

G. Alpine vegetation--nonforest vegetation of areas on mountains where there is insufficient heat for forest growth, as on Hawaii.

GROUP IV. AQUATIC ECOSYSTEMS

Collectively, aquatic plants and animals are at least as diverse as terrestrial forms. Although the concept of the ecosystem is equally applicable in the realm of aquatic biology, there are some difficulties in devising a classification of ecosystems that can be employed effectively in the survey and evaluation of natural areas. In part, these are the consequence of the philosophic problem of categorizing a very large number of essentially discontinuous fresh-water ecosystems. Further, although by no means unique to aquatic ecosystems, there is the practical problem of delineation of the ecosystem in terms of the area under consideration. For example, a lake as an ecosystem, in reality, should include the entire watershed and the plants and animals therein. The boundaries of a marine littoral ecosystem are even more difficult to delineate. Despite this type of difficulty, the concept of the ecosystem must nevertheless be applied vigorously in the evaluation of aquatic natural areas. A lake with an altered watershed is no longer natural, nor is a lagoon into which flows a polluted stream.

The system of themes used here for aquatic ecosystems is based extensively, although not completely, on geomorphological and other physical aspects of the environments of the aquatic ecosystems. Such a classification has obvious internal inconsistencies including many partially overlapping themes. Bearing in mind,

however, that the function of the entire scheme is to provide the basis for the inclusion of adequate and representative samples from the entire spectrum of natural history, such overlapping, rather than being a matter of concern, is one of insurance with respect to attaining the objectives of the system. It is only to be recognized that the system of themes for aquatic ecosystems has a structure that differs philosophically from that of the themes from terrestrial ecosystems.

Theme 29. Marine environments

Among the purely marine environments that can be included in protected areas, it is, of course, extremely difficult to divorce geological from biological influences. This theme is based on important changes in the biological community associated with relatively minor changes in substrate or exposure to wave action. Most conceivable marine sites will fit within the following divisions of this theme:

Exposed coastline and rocky substrate. A complex ecosystem characterized by maximum development of sessile animals and benthic algae (especially Postelsia). Wave action is severe; a splash zone is prominent; zonation is generally an obvious environmental feature. Examples: Cape Arego, Oregon; and possibly Point Loma at the entrance to San Diego Harbor, California.

Exposed coastline with unconsolidated sediment. The animal community is simple, composed of organisms characterized by ability to burrow rapidly. Wave action, surf, tidal rips, and other water movements are severe. A plant community, at least in the ordinary sense, is nonexistent; the substrate consists of shifting sand or small pebbles.

Coral reefs. Examples may be found in the U.S. Virgin Islands, Florida, Hawaii, American Samoa, and Guam. Exposure varies (i.e., windward and leeward sides). Reefs may be classified further into fringing, barrier, and atoll reefs. The biotic community is among the most complex known but also one of the best integrated (See also Group 1, theme 11.)

Protected coastline with rocky substrate. Wave action is reduced in intensity. Zonation is often not very apparent. The splash zone may be reduced or absent. Examples: San Juan Island; many areas near Santa Barbara, California, including the Channel Islands.

Protected coastline with unconsolidated sediment. Included here are areas of extensive sand flats characterized by soft-bodied burrowing animals. This theme may be difficult to separate from lagoons (below) except on the basis of currents and general degree of protection. Examples: Discovery Bay, Washington; Quincy Bay, Massachusetts.

Lagoons. These are often extensive bodies of water completely protected from wave or current action. Organisms usually include eelgrass, Zostera, growing in

extensive submersed meadows, and also characteristic animals. Examples: Mission, California; Sarasota Bay, Florida.

Tidal salt marshes. This is a type of community which has little diversity among plants and animals. Tidal salt marshes are often underlain by extensive salt-marsh peat; they are frequently characterized by endemic or specific mammal or bird populations. Examples: Spartina marshes, Sapelo Island, Georgia, Salicornia - Distichlis marshes, almost any bay in California.

Mangrove swamps. To a great extent these are the tropical replacements of the salt marshes. They are dominated by woody plants usually with stilt roots or pneumatophores. They occur in quiet tidal waters. Examples: Everglades National Park; all high Caroline Islands (Trust Territories).

Areas with extensive kelp beds. These are submarine forests with enormous brown algae in whose holdfasts live complex animal communities. Examples: much of the Pacific coast.

Theme 30. Estuaries

Estuarine ecosystems occupy the portion of rivers and/or arms of the sea between the head of tidal fluctuation and the open sea. They are characterized by marked gradients in salinity. The gradient in salinity and the tidal movements provide a series of habitats containing plants and animals that exemplify the transition from marine to fresh-water forms and from aquatic to terrestrial. Succession and the consequences of siltation are well illustrated. Relict forms may find in estuaries refuge from the forces of extinction. Isolation and partial isolation with their evolutionary consequences may be observed. In some cases, at least, this theme overlaps with, or is closely related to, lagoons, tidal salt marshes, and mangrove swamps in Theme 29, or deltas in Theme 33.

Theme 31. Underground systems

Caves and underground streams and lakes are the most common underground ecosystems. Unusual, endemic or rare species often occur here. Beetles, crayfish, millipedes, and amphipods are some examples of such fauna. Limited gene pools within a cave system has sometimes resulted in different rates of evolution. Thus, underground ecosystems can be important "evolutionary laboratories". Examples: Mammoth Cave National Park.

Theme 32. Lakes and ponds

A single lake may present many characteristics and may typify different kinds of biological and geological interaction. The following divisions are based extensively on the ways in which biological characteristics of a lake are influenced by a variety of physical factors in the environment, including geologic origin, location, climate, size (area and depth), and the chemical content of the water.

Large deep lakes. Large deep lakes are of interest and importance because of peculiar features with respect to stratification and restricted circulation, and because a relatively large fraction of the water mass is below the photosyntheic zone. Example: Lake Tahoe, Nevada.

Large shallow lakes. In contrast to large deep lakes, these lakes tend to circulate more freely. Much more of the water is within the photosynthetic zone. Other factors being similar, such lakes are more productive. They are often major breeding sites for aquatic birds. Plant communities of the more eutrophic large lakes are characterized by an abundance and diversity of forms. Examples: Mille Lacs and the Red Lakes, Minnesota; Salton Sea, California. (Obviously there is a continuous spectrum between shallow and deep lakes.)

Lakes of complex shape. A lake with complex shape, but with essentially uniform type of water, frequently presents excellent opportunities for observations of the effects on diverstiy and productivity, such as basin morphology, type of shore, and type of bottom. Included are lakes with multiple basins and systems of interconnected lakes.

Crater lakes. Because of their origin, the morphology of their basins and the physical and chemical properties of their waters, many of these lakes tend to be extremely oligotrophic. They are usually isolated and have extremely small watersheds. Example: Crater Lake, Oregon.

Kettle lakes and potholes. Such lakes vary considerably in trophic state. Frequently they support a varied and abundant aquatic vegetation and are attractive to species of birds that require isolated aquatic or semiaquatic breeding territories.

Oxbow lakes. Attention should be given to the degree of trophic development and the rate of replacement by terrestrial communities. The more eutrophic oxbow lakes may be important breeding sites for waterfowl.

Dune lakes. Again attention should be given to the rate of replacement by terrestrial communities. The interpretive value of such lakes is obvious.

Sphagnum-bog lakes. Careful selection can give important illustrations about the evolution from aquatic communities to fens to bogs.

Saline lakes. Saline lakes frequently contain unique communities of great interest and scientific value. They illustrate well the concept that the watershed is a part of the lake ecosystem.

Lakes fed by thermal steams. See Thermal waters, Theme 33.

Tundra lakes and ponds. These are, in reality, a part of the tundra ecosystem (Group III, Theme 20). It includes a large fraction of the breeding North

American geese and some other waterfowl. Low density is compensated by large total area. From the aspect of aquatic biology, the shallow nature of these bodies and the long winter freeze exert distinctive and interesting effects on the communities therein.

Swamps and marshy areas. Properly selected examples will provide excellent illustrations of the evolution of aquatic communities. These areas support an abundance and diversity of animal life, including many interesting species of birds and other animals. (They may be permeated by streams, ponds, and puddles.)

Sinkhole lakes. These are of importance and interest because of their origin from collapsed caves and because of previous or continuing association with underground stream systems.

Unusually productive lakes. See Large shallow lakes, kettle lakes and pot-holes, and oxbow lakes. Example: Upper Klamath Lake, Oregon.

Lakes of low productivity and high clarity. See large deep lakes and crater lakes. Examples: Crater Lake, Oregon; many montane lakes in Colorado.

Theme 33. Streams

Flowing waters are powerful molders of the Earth's crust and diverse habitats for life. As in the case of lakes and ponds, the biologic characteristics of streams are determined extensively by the physical properties of the stream-bed and by the nature of the watershed. Streams are characterized within the following divisions of this theme:

Rapidly flowing steams. These are of varying size and may have both gravel and rock bottoms. Such streams contain distinctive, specialized forms.

Slow meandering steams. These also include streams of varying sizes. Obviously, there is a spectrum of types between slow and rapid streams.

Deltas (both at seashore and at lakeshore). Deltas are often of major importance as breeding areas for waterfowl and shore birds. (See also estuaries.)

Springs. Especially important are springs in the desert or steppe, and those whose outflow disappears into the Earth without connection to other bodies of water.

Thermal waters. These ecosystems contain organisms with unusual and biologically important thermal adaptations. Examples: springs and warm streams in Yellowstone and Mount Rainier National Parks.

As the nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural and cultural resources. This includes fostering wise use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for enjoyment of life through outdoor recreation. The department assesses our energy and mineral resources and works to ensure that their development is in the best interests of all our people. The department also promotes the goals of the Take Pride in America campaign by encouraging stewardship and citizen responsibility for the public lands and promoting citizen participation in their care. The department also has a major responsibility for American Indian reservation communities and for people who live in island territories under U.S. administration.

NPS D-545 September 1990
