3 Fwd_ Review process for sea level_storm surge p....pdf
Hi John:

This sea level/storm surge projections dataset is somewhat unique for NPS & we are at the point we need to establish the internal NPS review process. Can we set a time to discuss?

Some background information is in the following email from PI- Dr. Maria Caffrey. Patrick Gonzalez has been the WASO contact on this 3 year NRFS project.

Thank you!

-rebecca

Subject: Review process for sea level/storm surge project
To: Rebecca Beavers <rebecca_beavers@nps.gov>

Rebecca,

I'm currently finishing up my draft report for my sea level and storm surge project and am starting to look ahead to how this should all be reviewed. I expect that the findings for this project have the potential to impact a lot of management decisions for the 118 coastal park units involved in this study. I've already received a lot of questions and requests to share my data from folks working on other NPS projects for things like:

- Foundation documents
- State of the parks reports
- The Western Carolina project
- DAB projects
I'm also scheduled to present on this in the CCRP webinar series later in the fall. I anticipate that I will have the first draft of the report to you by Friday (8/5). The GIS data is all ready to review right now. Doug Wilder made an online viewer for reviewers:

The individual GIS files can also be accessed through the NPS FTP site that I will send along to you in another email (the FTP site won't let me attach a link here).

How would you like to proceed with reviewing everything?

8 Re_ First draft is done!.pdf
Hi Amanda:

After I (& you, as well, if you have the time) review this report for typos & initial changes- the science team will get first review of this document. Your request for Franks Hays should be be a sample application for this report and related communication products.

Yay!!

You can access it here: https://www.dropbox.com/sh/dwd3uudowu4io1/AADjesLINuPviKbzRo3VcXa9a?dl=0

It's the file called "Sea Level Change Report Draft_August 2016.docx"

I'm sure it still has a bunch of typos all over it (I'm kinda delirious right now from writing it at the moment), so I will go back and check it for typos when I get back, but you're welcome to check it out and let me know if I'm missing anything significant.

See you in a few weeks.

Welcome back. It's great to see this info coming together.

My initial comments are uploaded to: N:\GRD\Programs\Climate Change - Beavers & Brunner\Caffrey Sea Level Projections\report

We can discuss on Thursday or Friday.

Amanda, Patrick,

Here is the draft report. I have included an excel spreadsheet for your comments so I don't have to try and combine four versions of track changes from everyone (I'll be emailing Rob and Steve for their comments separately). Please try to get your reviews back to me by 9/16/16.

Have a great labor day weekend!

Fort Collins, Colorado
The National Park Service, Natural Resource Stewardship and Science office in Fort Collins, Colorado, publishes a range of reports that address natural resource topics. These reports are of interest and applicability to a broad audience in the National Park Service and others in natural resource management, including scientists, conservation and environmental constituencies, and the public.

The Natural Resource Report Series is used to disseminate comprehensive information and analysis about natural resources and related topics concerning lands managed by the National Park Service. The series supports the advancement of science, informed decision-making, and the achievement of the National Park Service mission. The series also provides a forum for presenting more lengthy results that may not be accepted by publications with page limitations.

All manuscripts in the series receive the appropriate level of peer review to ensure that the information is scientifically credible, technically accurate, appropriately written for the intended audience, and designed and published in a professional manner. This report received formal peer review by subject-matter experts who were not directly involved in the collection, analysis, or reporting of the data, and whose background and expertise put them on par technically and scientifically with the authors of the information.

Views, statements, findings, conclusions, recommendations, and data in this report do not necessarily reflect views and policies of the National Park Service, U.S. Department of the Interior. Mention of trade names or commercial products does not constitute endorsement or recommendation for use by the U.S. Government.

This report is available in digital format from the Climate Change Response Program website (http://nps.gov/orgs/ccrp/index.htm), and the Natural Resource Publications Management website (http://www.nature.nps.gov/publications/nrpm/). To receive this report in a format optimized for screen readers, please email irma@nps.gov.

Abstract/Executive Summary

Changing relative sea levels and potential increasing storm surges due to anthropogenic climate change present many challenges to land managers. This report summarizes work done by the University of Colorado in partnership with the National Park Service to combine, compare, and contrast different sea-level change projections from the United Nations Intergovernmental Panel on Climate Change (IPCC) and storm surge scenarios using National Oceanic and Atmospheric Administration (NOAA) storm surge models. This report covers how these models are used to protect coastal units that have recently recovered from storm damage, such as the Statue of Liberty in New York. Both the IPCC and NOAA have established their own climate change scenarios, however this research will be the first to combine these results to show how storm surge could propagate in the future using bathtub models. These scenarios result in significantly different inundation outcomes. In addition to using multiple sea level and storm surge scenarios; multiple time horizons (2030, 2050 and 2100) were studied. The National Capital Region is expected to experience the highest average rate of sea level change by 2100, although the coastline adjacent to Wright Brothers National Memorial in the Southeast Region is projected to experience the highest sea level rise by 2100. The Southeast Region is also expected to experience the highest storm surges based on historical data and NOAA storm surge models.

These results have far reaching implications for adaptation and mitigation strategies for lands managed by the National Park Service.
Acknowledgments

This project was funded using funds from the NPS Servicewide Comprehensive Call (FY2013–2015) and was augmented by funds from the Natural Resource Stewardship and Science Directorate’s Geologic Resources Division and Climate Change Response Program. We would like to thank the members of the communication advisory team (Lynda Bell, Ann Gallagher, Will Elder, Janet Cakir, Stanton Enomoto, Matt Holly, Shawn Norton, Larry Perez, and Ryan Stubblebine) and science advisory team (Amanda Babson, Patrick Gonzalez, Steve Nerem, and Rob Thieler) for their time and input into this project.

We would also like to thank the Susan Teel and Caroline Rohe at Gulf Islands National Seashore for their assistance designing two waysides. Likewise, we also thank Julie Whitbeck, Aleutia Scott, Kristy Wallisch, and Stacy Meyers for helping design, review, and install a wayside at Jean Lafitte National Historical Park and Preserve. Elizabeth Rogers and Kathy Krause helped design a wayside for Fire Island National Seashore.

We would also like to thank xxx for their assistance in editing and reviewing this document.

List of Terms

The following list of terms are defined here as they will be used in this report.

Flooding: The temporary impoundment of water on the land.

Inundation: The permanent impoundment of water on what had once been dry land.

Isostatic rebound: A change in land level caused by a change in loadings on the Earth’s crust. The most common cause of isostatic rebound is the loading of continental ice during the Last Glacial Maximum in North America. The North American land surface is still moving after the melting of this continental ice in an effort to return to equilibrium with its original pre-loading state.

National Park Service unit: Property owned or managed by the National Park Service.

Relative sea level: Where the water level can be found compared to some reference point on land. This term is most frequently used in discussion of changes in relative sea level. A change in relative sea level could be caused by a change in water volume or a change in land level (or some combination of these two factors).

Sea level: The average level of the seawater surface.

Sea-level change: This term is frequently used in reference to relative sea-level change. This is the product of two main factors, 1) an increase in the volume of ocean water, and 2) a change in land level. These two factors can be broken down further into other drivers that will be discussed in greater detail in other sections. This term is sometimes mistakenly confused with the term sea-level rise.

Sea-level rise: An increase in sea level. This is the result of an increase in ocean water volume caused principally by melting continental ice and thermal expansion. This term is not to be confused with increasing relative sea level, which can also be caused by decreasing land levels.
Introduction

Global sea levels are rising. While sea levels have been gradually rising since the last glacial maximum approximately 21,000 years ago (Clark et al. 2009, Lambeck et al. 2014), the onset of anthropogenic climate change has significantly increased the rate of global sea-level rise (Grinsted et al. 2009, Church and White 2011, Slangen et al. 2016, Fasullo et al. 2016). As human activities release carbon dioxide (CO₂) into the atmosphere we can expect the Earth’s atmosphere to continue to warm over the next century (IPCC 2013, Mearns et al. 2013, Melilo et al. 2014). As the atmosphere warms we anticipate sea levels to also rise; however, the rate of warming depends on a number of factors that have been categorized by the Intergovernmental Panel on Climate Change (IPCC) into four different representative concentration pathways (RCPs; Meinshausen et al. 2011). These RCPs are newly defined climate change scenarios that were first introduced in the IPCC’s most recent climate change report (IPCC 2013) and will form the basis of this report. The aim of this report is to discuss how anthropogenic climate change will impact our coastal zone via sea-level change and storm surge. As temperatures change, sea levels will rise due to a number of factors that will be discussed in greater detail; however, while sea levels are incrementally rising we can also expect periods of coastal flooding caused by coastal storms and hurricanes to exacerbate the growing problem of coastal inundation (see list of terms).

When Hurricane Sandy struck New York City in 2012 it caused an estimated $19 billion of damage to public and private infrastructure (Tollefson 2013). While the amount of damage from this storm might seem to be extreme, we can expect a 1/100 year storm surge to cost $2−5 billion and a 1/500 year storm surge to cost $5−11 billion (Aerts et al. 2013). Looking ahead to the future we can expect storms to become more intense (Mann and Emanuel 2006, Knutson et al. 2010, Lin et al. 2012, Ting et al. 2015). When this change in storm intensity (and therefore, storm surge) is combined with sea-level rise, we expect to see increased coastal flooding and the permanent loss of land across much of the United States coastline.

Peek et al. (2015) estimated that the cost of sea-level rise in 40 National Park Service units could be in excess of $40 billion if these units were exposed to one-meter of sea-level rise. The aim of this report is to examine 118 coastal park units to: 1) quantify precisely how much sea-level rise they can expect over the next century based on the latest IPCC (2013) models, and 2) how could storm surge generated by hurricanes could also impact these parks.

Format of This Report

This report is separated into five sections: introduction, methods, results, discussion, and conclusion. Results per park will be presented alphabetically by region. The 118 park units studied for this project cover six administrative regions: the Northeast, Southeast, National Capital, Intermountain, Pacific West, and Alaska. Funding for this project did not include projected changes in lake levels, although we recognize that interior waterways and lakes, especially the Great Lakes, are also vulnerable to climate change. Further explanation on how to access the data from this project can be found in the methods sections and accompanying appendices.
**Frequently Used Terms**

Definitions of the most basic terms used in this report can be found on page viii. However, some terms require some greater explanation for their use. We are following the advice of Flick et al. (2012) in differentiating between the terms *flooding* and *inundation*. While many choose to use these terms interchangeably, we use the term *flooding* to describe the temporary placement of water on land. This is usually the result of storm activity and other short-lived events, such as periodic tidal action, and will therefore be used here in reference to the effects of a storm surge on land. *Inundation* is used to refer to the gradual permanent submergence of land that will occur due to sea-level rise.

Furthermore, the terms sea-level rise and sea-level change are also used differently. *Sea-level rise* refers only to rising water levels resulting from an increase in global ocean volumes. In most parts of the United States this increase in water volume will lead to increasing relative sea levels. However, in some parts of the country relative sea level is *decreasing* due to isostatic rebound. Figure 1 shows current sea level trends based on tide gauge records for United States that span at least 30-years of data.

**Figure 1.** Sea level trends for the United States based on Zervas (2009). Trends are calculated for 2015 relative to global mean sea level. Each dot represents the location of a long-term (>30 years) tide gauge station. Green dots represent stations that are experiencing the average global rate of sea level change.
Yellow to red dots are experiencing greater than the global average (primarily driven by regional subsidence) and blue to purple dots are stations that are experiencing less than the global average (due to isostatic rebound or other tectonically-driven factors). Source: https://tidesandcurrents.noaa.gov/sltrends/slrmap.htm

The Southeast Region of Alaska is experiencing a decrease in relative sea level. Alaska’s crust is still rebounding following the melting of large volumes of ice that had been stored on land for centuries to millennia. Alaska is also very tectonically complex with a large number of faults that contribute to this crustal motion. Even though the volume of water in this region is increasing, the rate of sea-level rise is not enough to keep up with the rate of land-based movement resulting in a decrease in relative sea level. Whether the rate of land-based motion will continue throughout this century will be discussed in further detail in other chapters; however, this is why we use the term sea-level change as a more inclusive term that better reflects regions that will experience a decrease in relative sea level (at least in the early part of this century) as well as those that will have to deal with increasing relative sea levels.

Methods

This report reflects the work of a three-year project that began in 2013. 118 National Park Service units were selected after consultation with regional managers who identified which units they considered to be vulnerable to sea level change and/or storm surge (Appendix C). Funding for this project required the following:

1. Calculate rates of sea level change over multiple time horizons for each park unit.
2. Estimate potential exposure to storm surge using the National Oceanographic and Atmospheric Administration (NOAA) Sea, Lakes, and Overland Surge from Hurricanes (SLOSH) Model.
3. Create waysides communicating about the impact of climate change in the coastal zone for three National Park Service units.

A wayside is an exhibit designed to be installed outside for visitors to find out more information about a particular subject (https://www.nps.gov/hfc/products/waysides/). Four waysides were created for three National Park Service units: Gulf Islands National Seashore, Jean Lafitte National Historical Park and Preserve, and Fire Island National Seashore. These parks were selected after consulting with regional managers who recommended units that they felt had a need for a communication product and had communication staff who were available to work with staff at the University of Colorado in the design. The finished wayside designs are in Appendix D. Each wayside design is different because each wayside was customized to reflect the messaging and/or themes of each unit.
Sea-Level Rise Data

Sea-level rise is the product of a number of factors at work. As humans activities release more CO₂ and other greenhouse gases into the atmosphere, mean global temperatures will increase (IPCC 2013, Gillett et al. 2013, Frolicher et al. 2014). Rising global temperatures cause ice located on land and in the sea to melt. While the melting of sea ice is problematic from an oceanographic perspective (primarily because it will alter water temperatures and salinity), it is the melting of ice that is currently stored on land that will have the greatest impact on global sea levels.

Melting sea ice is not a cause of sea-level rise. Water level does not change when sea ice (ice wholly contained within water and not supported by land) melts. The phase shift of water from ice to liquid water does not displace an additional volume of water.

However, the melting of ice found on land, such as Greenland and Antarctica, is a significant driver of sea level rise. As ocean waters warm the density of these waters will also change causing thermal expansion. Thermal expansion is responsible for approximately 39% of sea level rise while melting ice contributed a further 47% from 1993 to 2010 (IPCC 2013). Other factors that also need to be considered are listed in Table 1.

aData until 2009, not 2010.
bThis is not included in the total because these numbers have already been included in the Greenland ice sheet.
cThis is calculated as observed global mean sea level rise – modeled glaciers – observed land water storage. See table 13.1 in IPCC (2013) for more details.

Sea level rise projections for this project follow a process-based model approach. This process-based approach generates data based on the underlying processes that are responsible for sea level rise. This is in contrast to semi-empirical models that use observations in combination with any number of other variables or theoretical considerations, which in some cases include expert elicitations (surveys or interviews with other professionals to gauge their opinion) (Rahmstorf 2010, Orlic and Pasaric 2013). The IPCC cites a number of semi-empirical projections in their most recent report (IPCC 2013), but they choose to use coupled atmosphere-ocean general circulation models (AOGCM). AOGCMs are able to simulate the processes of change rather than relying on statistical inferences.
that make up the semi-empirical approach. AOGCMs are considered a process-based technique, although some variables may have been derived using semi-empirical methods (IPCC 2013).

Local sea-level rise numbers for 2050 and 2100 were taken directly from the IPCC (2013) downscale AOGCM regional climate model (RCM). Many park units also require estimates for shorter time horizons that fit more closely with the expected lifetime of various projects, so sea level rise projections for 2030 were calculated using IPCC RCM data for each sea level rise driver shown in Table 2 downscale to 2030 for each RCP. All projections results are relative to the period 1986–2005 (see Appendix C for further discussion).

Table 2. Median values for projections of global mean sea level and its contributions in meters for 2100 (IPCC 2013).

\(^a\)Changes in ice mass derived through direct observation and satellite data.

The standard error (\(\sigma\)) for each site estimate was not calculated because it was beyond the scope of this project. However, it can be calculated using the following equation and data available from the IPCC (2013 supplementary material):

\[
\sigma_{\text{tot}}^2 = \left(\sigma_{\text{steric/dyn}} + \sigma_{\text{smb,a}} + \sigma_{\text{smb,g}}\right)^2 + \sigma_{\text{glac}}^2 + \sigma_{\text{IBE}}^2 + \sigma_{\text{GIA}}^2 + \sigma_{\text{LW}}^2 + \sigma_{\text{dyn,a}}^2 + \sigma_{\text{dyn,g}}^2
\]

Where: \(\text{steric/dyn}\) = the global thermal expansion uncertainty plus dynamic sea surface height; \(\text{smb}_a\) = the Antarctic ice sheet surface mass balance uncertainty; \(\text{smb}_g\) = the Greenland ice sheet surface mass balance uncertainty; \(\text{glac}\) = glacier uncertainty; \(\text{IBE}\) = the inverse barometer effect uncertainty; \(\text{LW}\) is the land water uncertainty; \(\text{dyn}_a\) = Antarctica ice sheet rapid dynamics uncertainty; and, \(\text{dyn}_g\) = Greenland ice sheet rapid dynamics uncertainty.

Initial data were exported as GeoTIFF files that could be manipulated in ArcGIS as simple bathtub models. A weighted average by shoreline was calculated for park boundaries that overlapped more than one data cell. A standard bathtub model approach was used to show the effects of sea level rise on top of mean higher high water. Areas of inundation and flooding are denoted in the maps in the blue. Additional low-lying areas that could be potentially inundated or flooded are shown in green.
These low-lying areas do not appear to have any inlet or other pathway for water, although they should still be considered vulnerable to exposure to either groundwater seepage or potential flooding via breaching. The lack of high-resolution DEMs and time constraints prevented us from attempting a dynamic modeling approach (see limitations below). Maps were created to illustrate inundation all park units for 2050 and 2100 under RCP4.5 and RCP8.5.

---

**Storm Surge Data**

NOAA SLOSH data estimate potential storm surge height (NOAA 2016). The NOAA SLOSH model is comprised of the following three products (P-Surge, MEOW, and MOMs) that utilize three different modeling approaches (probabilistic, deterministic, and composite) to estimate storm surge. P-Surge (also known as the tropical cyclone storm surge probabilities product) uses a probabilistic approach by examining past events to estimate the storm surge generated by a cyclone that is present and within 72-hours of landfall. It statistically evaluates National Hurricane Center data (calculated in part using a deterministic approach) including the official projected cyclone track and historical forecasting errors. It also incorporates astronomical tide calculations and variations in the radius of maximum wind into this estimate. These rates of motion variables are then fit to a Cartesian or polar (depending on the location) grid (Jalesnianski et al. 1992).
The Maximum Envelope of Overwash Water (MEOW) calculates flooding using past P-Surge data to create a composite estimate of the potential storm surge generated by a hypothetical storm. This product generates a worst-case scenario based on a hypothetical storm category that includes forward speed, trajectory of the storm when it strikes the coastline, and initial (mean vs. high) tide level that will also incorporate any historical uncertainty from previous landfall forecasts.

The final SLOSH product is the MOM (Maximum of MEOWs) model. MOM is a further composite approach that uses the forward speed, trajectory, and initial tide level data that is also used by MEOW to create a worst-of-the-worst scenario (or “perfect storm”). Storms are simulated for 32 regions (also known as operational basins, Figure 3) defined by NOAA. Data was imported into ArcGIS using the SLOSH display program. Maps were generated showing storm surge for all possible Saffir-Simpson hurricane categories for each site. While most sites had data for Saffir-Simpson hurricane categories 1–5, a few sites, such as Acadia National Park, were missing the highest category. NOAA did not model this scenario because it is considered extremely unlikely at a location that far north in the Atlantic Ocean.

SLOSH MOM was used to estimate potential storm surge in 79 coastal park units. Unfortunately MOM data do not exist for the remaining 39 units, so we supplemented this with data from Tebaldi et al. 2012 wherever possible. Tebaldi et al. (2012) used 55 long-term tide gauge records to calculate potential sea level and storm surge estimates. We used the current 50-year and 100-yr return level data from their paper for any parks near to a tide gauge. Unfortunately we were unable to use either Tebaldi et al. (2012) or SLOSH MOM data for the Alaskan, Guam, and American Samoa park units.

Storm surge models were combined with the mapped sea level rise data to get a rough idea of how these regions could be exposed to flooding occurring later in the century on top of inundation. We
used historical hurricane data from the International Best Track Archive for Climate Stewardship (IBTrACS; Knapp et al. 2010) to ascertain the highest Saffir-Simpson category hurricane to strike within 10 miles of each park unit. We then used the MOM estimate for a storm surge one category higher than anything that had struck the park historically (based data spanning 1842–2014; Appendix E, Table E3). By using one storm category higher than historical data we hoped to approximate what could happen as storms are expected to be more intense due to anthropogenic climate change in the future (Emanuel 2005, Webster et al. 2005, Mendelsohn et al. 2012). However we would recommend caution in using these combined maps for any detailed planning due to the limitations that will be discussed further in the following section of this report.

Limitations
While every effort has been made to use the best available data and techniques, all projects of this nature have limitations that should be clearly delineated to ensure that these data are interpreted correctly.

Every effort has been made to incorporate any parks, such as Harriet Tubman Underground Railroad National Monument, that were established after work began, although some maps might be missing due to lack of available boundary data in new units.

We used a bathtub modeling approach to map the extent of sea level rise and storm surge over every unit. Bathtub modeling simply simulates how high up or inland water will go under different climate scenarios. It does not take into account changes in topography or other environmental or manmade systems that will occur in response to encroaching water. While bathtub models are the most widely used technique for modeling inundation, it is also a more passive technique of simulating how sea level rise will impact a landscape (Storlazzi et al. 2013). Dynamic models could model changes in flow around buildings or estimate how topographic features such as dune systems will migrate in response to inundation and flooding; but dynamic models also vary in their methods, which can be a severe limitation if trying to standardize data for comparison and management.

Even though SLOSH MOM has the widest geographic storm surge coverage of any model in the US, storm surge data are not available for every part of the coastline. Every effort has been made by this project to bridge any gaps where SLOSH MOM does not exist. While the Tebaldi et al. (2012) data cover the California, Oregon, Washington, and southern Alaskan coastlines, it does not give any information for the northern Alaskan, American Samoan, or Guam coastlines. These coastlines are vulnerable to storm surge but we could not find data that we were satisfied were accurate enough to be included in our mapping efforts. Furthermore, combined sea level and storm surge maps are only intended as a rough guide of how flooding by storm surge on top of permanent inundation due sea level rise and should be used with caution. As more of the coastline becomes inundated we can expect coastal flooding to also change accordingly. The SLOSH model is a probabilistic approach that uses previous storms to estimate future storm surge. It cannot take into account any changes in future basin morphology that could affect the fluid dynamics and propagation of coastal flooding.
SLOSH MOM is modeled using mean sea level (0 m NAVD88) and what NOAA terms “high tide” (which is not tied to the local tidal datum, but is actually a round number based on the average high tide for the region that was modeled). Jalesnianski et al. (1992) estimate surge estimates to be accurate +/- 20%, although Glahn et al. (2009) discuss how others have found the P-Surge model to be more accurate than originally estimated. All of these things must be kept in mind when using these numbers for mapping.

Land Level Change

It is important to include changes in land level while interpreting changes in sea level. The IPCC (2013) does not include changes in relative sea level in their calculations of sea-level change. Our sea level rise results do not include how changes in land level will change over time. Land level change is an important variable when calculating relative sea level. Land levels have changed over time in response to numerous factors. Changes in various land-based loadings, such as ice sheets during the last glacial maximum, on the continents has been a significant cause of land level change in the U.S. Post-glacial isostatic rebound is the result of this pressure placed on the Earth’s crust by the ice sheets and is still causing land levels to change. Land level can also be altered by other factors such as tectonic shifts particularly along Alaska and continental U.S. Pacific coastline. The aforementioned drivers can often prompt either a relative increase or decrease in land level depending on location. Other factors such as aquifer drawdown and the draining of coastal swamps can create decreases in relative land level.

Quantifying how land levels are changing is difficult given the paucity of data available prior to modern satellite data. This data need will be relieved by the release of a NASA study on land-based movement in 2017 (Nerem per. comm.). This NASA report will provide numbers for land-based movement across the country. These numbers should be incorporated with the sea-level rise numbers in this report once they are released in 2017. These numbers can be combined with the numbers in this report in the following equation (after Lentz et al. 2016):

$$aE = E_0 - e_i + R$$

Where; $ae$ is the adjusted elevation, $E_0$ is the initial land elevation, $e_i$ is the future sea level for either 2030, 2050, or 2100, and $R$ is the current rate of land movement due to isostatic adjustments.

In the interim, tide gauges can provide data regarding changes in land level, but should be used cautiously. We have listed tide gauge data for the rate of change in land level for tide gauges nearest to all units for this study in Appendix E; however, only Fort Pulaski National Monument and Fort Point National Historic Point have a long-term tide gauge on site. This lack of nearby long-term data can limit the accuracy of these numbers if they are applied to sea level change projections for almost all other parks units. Land level changes were only reported for long-term tide gauges that had at least thirty years of data in order to ensure a statistically robust dataset. Based on these limited records we estimate that seven park units are currently experiencing decreasing relative sea levels (Figure 4; Glacier Bay National Park, Glacier Bay Preserve, Katmai National Park, Kenai Fjords...
National Park, Lake Clark National Park, Sitka National Historical Park), although we cannot be
certain of this number given that many of park units are some distance from a tide gauge. We expect
the release of the NASA data (Nerem per comm.) to help refine these estimates.

Figure 4. The estimated percentage of park units that currently experience decreasing relative sea
levels (orange) versus those with increasing relative sea level (blue).

It is strongly recommended that you discuss the applicability of these land level numbers with a
natural resources manager or similar expert to ensure that the nearest tide gauge to your project site is
appropriate. In selecting an appropriate tide gauge to use a number of variables must be taken
including oceanographic setting, length of the record, completeness of data, and geography of the
coastline. A decision was made by the science team for this project to not set a threshold for how
close a park unit should be to a long-term tide gauge based on the aforementioned considerations.

Where to Access the Data

All GIS data from this project will be uploaded on www.irma.gov for archiving by park. Non-GIS
users can access the data discussed in this report using our online map viewer at:

https://www.nps.gov/subjects/climatechange/sealevelchange

The raw IPCC (2013) data can be downloaded using the following link:

http://ipcc.ch/report/ar5/wg1/docs/ar5_wg1_ch13sm_datafiles.zip
Results

Sea level and storm surge maps are in Appendices A and B. A full list of the 118 park units used for this study can be found in Appendix D along with a table listing sea level rise projections per park unit. Following the methods outlined above we found that sea level rise will average between 0.45 m (RCP2.6) and 0.67 m (RCP8.5) by 2100. However, this number masks how these data will vary geographically. Figure 5 describes these data in more detail by breaking down sea level estimates by region. The error bars in Figure 5 denote the standard deviation for each average per region, which further reveals how these numbers can vary. A high standard deviation and range signals that sea level estimates vary between units, whereas a low standard deviation and small range are expected in smaller regions where sea level rise estimates do not cover such a large geographic area.

Figure 5. Projected future sea level by region for 2100 under RCP8.5. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each average. Blue bars mark the full range of sea level estimates for each region. These averages do not include the impact of land movement.

Based on the averages per region we found that the shoreline within the National Capital Region is expected to experience the highest sea level rise (0.80 m RCP8.5 2100), although this number does not include changes in land level over the same time interval. The shoreline near Wright Brothers National Memorial in the Southeast Region has the highest overall projected sea level rise (0.82 m RCP8.5 2100). Glacier Bay Preserve and Klondike Gold Rush National Historical Park are tied for lowest projected sea level rise at 0.33 m using RCP8.5 for 2100. The Alaska Region also has the highest standard deviation among park units. The National Capital Region conversely has very little standard deviation due to the compact nature of the region that meant that all of the parks units listed fell within the same raster cell. This is not to say that all of the parks will experience exactly the same amount of sea level rise, but that the IPCC model projected that sea levels could rise up to an average 0.80 m (RCP8.5) above waterline for that region by 2100. These differences among the National
Capital parks is illustrated in our sea level rise maps which will be discussed in further detail in the National Capital section of this report.

Comparing RCP8.5 data for 2030 and 2050 (Figures 4 and 5, respectively) shows the National Capital Region tied with the Northeast Region in 2030 based on average projected sea level rise, however the National Capital Region ranks highest in 2050. The Alaska Region ranks lowest for all three time intervals followed by the Pacific Northwest region, Intermountain Region, and Southeast Region. The Northeast Region comes ranks second highest for 2050 and 2100.

Figure 6. Projected future sea level by region for 2030 under RCP8.5. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each average. Blue bars mark the full range of sea level estimates for each region.

Figure 7. Projected future sea level by region for 2050 under RCP8.5. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each average. Blue bars mark the full range of sea level estimates for each region.
Storm surge was mapped for 79 park units. Storm surge data were combined with sea level rise projections to approximate how much area could be exposed to flooding on top of inundation. We used data for one storm category higher than the highest historical storm for our combined maps. Table E3 in Appendix E lists the highest historical storm for each park unit. 31 park units did not have a historical storm path travel within 10 miles of their boundaries, so a Saffir-Simpson hurricane 1 was simulated for these locations. The lack of a historical storm does not mean that these parks are not subject to strong storms. It may merely be that these parks are in regions that either do not have extensive historical records or they experience strong storms that are classified differently, such as nor’easters.

The Southeast Region has the strongest historical storms (average of highest recorded storm categories = 2.79), followed by the Intermountain Region (average = 2.33), National Capital Region (average = 1.90), and the Northeast (average = 1.03). None of the historical data intersected with the 10 miles buffers around the Alaska region parks. The Pacific West Region has experienced some tropical depressions, particularly in Hawaii, but most of their storm surges are driven by other phenomena, such as midlatitude cyclones or extreme tides (sometimes colloquially referred to as a king tide). The strongest (highest winds) and most intense (lowest pressure at landfall) recorded historical storm to have impacted a park unit was the “Labor Day Hurricane” that passed within 10 miles of Everglades National Park in 1935. However, while this storm may have been the highest intensity storm it is certainly not the most damaging or costly storm in National Park Service history.

Northeast Region

Figure 8 shows how the range of sea level projections for the Northeast Region for 2100. It is projected to average between 0.49 m (RCP2.6) and 0.74 m (RCP) of sea level rise by the end of the century. Colonial National Historical Park, Fort Monroe National Monument, and Petersburg National Battlefield are all tied for the coastline with the highest projected sea level rise in 2050 and 2100. They are also tied along with Edgar Allen Poe National Historic Site, Fort McHenry National Monument and Historic Shrine, Independence National Historical Park, and Thaddeus Kosciusko National Memorial as parks near coastline with the highest projected sea level rise for 2030.

However, while these parks may have ranked highly, so caution should be used when analyzing these results. Many of these parks do not have coastline and so these projections are based on sea level rise for the coastline adjacent to these parks. The maps in Appendix A show how these projected numbers will impact each of these parks. Colonial National Historical Park, Fort McHenry, and Fort Monroe National Monument are the only park units that contain coastline with their boundaries. Acadia National Park had the lowest projected rates of sea level rise for 2030 (0.08–0.10 m), 2050 (0.14–0.19 m), and 2100 (0.28–0.54).
Figure 8. Projected future sea level by 2100 for the Northeast Region under all of the representative concentration pathways. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each average. Blue bars mark the full range of sea level estimates for each category.

The highest recorded storm to have travelled within 10 miles of any of the 29 parks units identified for study was an officially unnamed hurricane in 1869 known colloquially as Saxby’s Gale that was classified as a Saffir-Simpson 3 hurricane. The storm path passed Boston National Historical Park and Roger Williams National Memorial. Figure 9 shows the estimated extent of a storm surge from category 3 hurricane striking Boston Harbor Islands National Recreation Area at mean tide.

Figure 9. Estimated storm surge created by Saffir-Simpson category 3 hurricane occurring at mean tide near Boston Harbor Islands National Recreation Area.
Southeast Region

The southeast region can expect to have some of the more intense (highest Saffir-Simpson storm category) storm over this century. Historically, the region has the highest intensity storms; although Everglades National Park has recorded a category 5 hurricane within 10 miles of its boundary, Figure 10 shows how it would only need to be struck by category 2 hurricane to completely flood the park.

Figure 10. SLOSH MOM storm surge maps for a Saffir-Simpson category 1 (left) versus category 2 hurricane striking Everglades National Park at mean tide.

Combining such large storm surges with sea level rise highlights how exposed many of the Southeast Region park units are. It should also be considered that sea level rise projections do not include changes in land level. We recommend waiting for the forthcoming NASA report (Nerem per comm.) on land level before applying any numbers for planning; however, using table E1 from Appendix E as a rough guide changing land level for parks near tide gauges can be evaluated. The Eugene Island, Louisiana tide gauge’s current rate of sea level rise is the highest in the country at 9.65 mm/yr owing in part to the large rate of subsidence in the region (Figure 1). Using the nearest tide gauge to Jean Lafitte National Historical Park and Preserve (Grand Isle, Louisiana, gauge 8761724) we can estimate that land will subside by 7.60 mm/yr. Applying this estimate of subsidence (using a baseline of 1992) to our RCP8.5 projections, the park could experience approximately 0.41 m of relative sea level rise by 2030 followed by 0.69 m by 2050 and 1.50 m by 2100.
Our projections list Wright Brothers National Memorial’s nearest coastline as having the greatest sea level rise by 2100 (0.82 m RCP8.5), but given the elevation of the park, this will still not inundate a large area of the memorial. However this could be more of a problem if this rise in water level is combined with other factors, such as a storm surge. The park will be almost completely flooded if a category 2 or higher hurricane strikes on top of the inundation from sea level rise.

Nearby Cape Hatteras and Cape Lookout National Seashores are projected to experience up to 0.79 m and 0.76 m, respectively (RCP8.5) of sea level rise by 2100. Both of the aforementioned units have shoreline as part of their boundaries, which means these rises in sea level will result in large areas of inundation. While these national seashores may rank slightly lower than Wright Brothers National Memorial for sea level rise, they serve as example of how caution must be used when using these numbers to assess which park units are most vulnerable to sea level rise. Other factors, such as percent of exposed land, changes in land movement, and adaptive capacity must also be taken into account for vulnerability analysis (Peek et al. 2015).

**National Capital**

National Capital Region has very little variability in projected sea level rise because all of the park units selected for study are all adjacent to the same section of coastline that was modeled. Their proximity also explains why they all share the same storm history. Despite these similarities, the way these numbers will impact each individual park unit will vary based on the topography of Washington D.C. The strongest storm to ever pass within 10 miles of the National Capital Region parks was as Saffir-Simpson category 2 hurricane that struck the city in 1878. While 1878 storm caused relatively little damage, we can expect a significantly larger amount of damage if a similar storm struck the city again. Figure 11 shows the extent of flooding created a Saffir-Simpson category 2 hurricane. A storm surge measuring more than 3 m could travel up the Potomac River causing large amounts of flooding.
IPCC/SLOSH models showed either storm surge or sea level rise (or some combination of the two) impacting every park nominated for study with the exception of Harpers Ferry National Historical Park. Our mapping efforts revealed that Harpers Ferry National Historical Park located approximately 149 m above sea level is unlikely to experience any impacts of sea level rise due to its elevation and is unlikely to be damaged by storm surge from a hurricane from its relatively protected location behind several dams along the Potomac and Shenandoah Rivers. Harpers Ferry is potentially vulnerable to other climate change impacts, such as changing temperatures and precipitation.

Sea level rise alone is not expected to spread very far into Washington D.C., although a large section on the east side of Theodore Roosevelt Island will be inundated. However, storm surge flooding on top of this sea level rise would have widespread impacts.

**Intermountain Region**

The Intermountain Region covers mostly inland park units stretching from Texas to Montana. Only three park units in Texas could be nominated for a study of this nature: Big Thicket National Preserve, Palo Alto Battlefield National Historical Park, and Padre Island National Seashore. Padre
Island National Seashore is likely to experience the greatest effects of sea level and storm surge out of the three park units. Sea level is projected to rise 0.46–0.69 m (RCP2.6–8.5, Figure 12) by 2100. The same amount of sea level rise is projected for the shoreline near Palo Alto Battlefield National Historical Park, but it is not expected to stretch inland enough to reach the park. Palo Alto Battlefield National Historical Park has no history of being within 10 miles of any hurricane, making the site unlikely to be flooded by storm surge. SLOSH MOM models for the park unit show that the region would have to have either a Saffir-Simpson category 4 hurricane striking at high tide or a category 5 hurricane striking at any tide in order for the park to experience any storm surge. Whereas Figure 13 shows how Padre Island National Seashore located on the shoreline to the east of Palo Alto Battlefield National Historical Park has been within 10 miles of a category 4 hurricane. SLOSH MOM data show that another category 4 hurricane that would likely flood almost the entire island if it struck again.

There is some potential for storm surge to travel up the Neches River and flood the southernmost part of Big Thicket National Preserve, although storm surge defenses in Beaumont, Texas to the south of the preserve are likely to buffer it from any surge. It is more likely that a hurricane would cause flooding over a wider area of the park via precipitation.

**Figure 12.** Projected future sea level by 2100 for the Northeast Region under all of the representative concentration pathways. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each average. Blue bars mark the full range of sea level estimates for each category.
Figure 13. A SLOSH MOM map showing storm surge height and extent created by a Saffir-Simpson category 4 hurricane striking the southwestern Texas region at mean tide. The dark green line around the island represents the boundary of Padre Island National Seashore.

Pacific West Region

The Pacific West Region identified 24 park units that could be vulnerable to sea level rise and/or storm surge. These units are located over a large area comprising California, Oregon, Washington, Hawaii, American Samoa, and Guam. The average projected sea level rise ranges between 0.40–0.58 m (RCP2.6–8.5) by 2100 for the whole region; however, there is a large standard deviation between these numbers (0.04–0.08 for RCP2.6–8.5, respectively) that belies how the park-specific projections vary across the region. War in Pacific National Historical Park in Guam has the highest projected sea level rise at 0.68 m (RCP8.5) by 2100. War in Pacific National Historical Park is also tied for highest projected sea level rise with almost all of the Hawaiian park units in 2030 and 2050.

At the other end of the spectrum the park units located around Washington’s Olympic Peninsula (Ebey’s Landing National Historical Reserve, Olympic National Park, and San Juan Island Historical Park) rank lowest for projected sea level rise. Sea level is projected to rise much more slowly in this region reaching a maximum 0.46 m (RCP8.5) by 2100. This is a region that is subject to tectonic shifts as well as continuing land movement due to isostatic rebound that further complicate sea level projections. Long-term tide gauge records at Neah Bay, Washington (gauge 9443090) and Tofino, Canada (gauge 822-116) show relative sea levels as currently decreasing while tide gauges in Port
Angeles, Washington (gauge 9444090), Victoria, Canada (gauge 822-101), and Seattle, Washington (gauge 9447130) show it to be increasing (Zervas 2009). Our projections show sea level in this region to rise throughout this century, although the release of the forthcoming NASA report (Nerem per comm.) could shed more light on this matter.

Modeling for storm surge is complicated by the lack of hurricanes to have stuck many of the parks in this region. Instead we chose to use data from Tebaldi et al. (2012) that includes anomalous surges that could be created by storms as well as other factors (sometimes referred to as king tides). Based on the Tebaldi et al. (2012) data, La Jolla, California (gauge 9410230) has the lowest 100-year storm surge measuring 0.95 m and Toke Point, Washington (gauge 9440910) has the highest 100-year storm surge (1.96 m) in the Pacific West Region. Tebaldi et al. (2012) did not analyze storm data for Hawaii, Guam, or American Samoa, although IBTrACS (Knapp et al. 2010) does have hurricane records for these areas. Only tropical depressions have been recorded within 10 miles almost all of the selected Hawaiian park units (Haleakala National Park, Hawaii Volcanoes National Park, Kalaupapa National Historical Park, Kaloko-Honokohau National Historical Park, Puukohola Heiau National Historic Site, and World War II Valor in the Pacific National Monument).

Alaska Region

The Alaska Region has the lowest average projected sea level rise (0.28−0.43 m by 2100) compared to the five regions described above. Glacier Bay National Park and Preserve and Klondike Gold Rush National Historical Park in southeastern Alaska share the lowest projected sea level rise (0.33 m RCP8.5 2100) while Bering Land Bridge National Preserve on the west coast of the state has the highest projected sea level rise (0.60 m RCP8.5 2100).

Figure 1 shows how current relative sea levels vary across the state. Land levels are rapidly rising in the southeast of the region due to isostatic rebound and other tectonic shifts. Current rates of relative sea level change in Skagway, Alaska are the lowest in the country; decreasing at an average rate of 17.59 mm/yr (Zervas 2009). The net result of these increasing land levels is decreasing relative sea levels for at least the early part of this century. Despite melting ice and other factors outlined in Table 1 that are adding to our ocean waters volume, the amount of rising water is not sufficient to keep up with the land level. Seven park units (Glacier Bay National Park, Glacier Bay Preserve, Katmai National Park, Kenai Fjords National Park, Lake Clark National Park, Sitka National Historical Park) have been identified as potentially having decreasing relative sea levels based on the nearest tide gauge data to each of these parks. None of these parks have long-term tide gauges that have data spanning at least thirty years. A great strength of using the IPCC (2013) process-based model approach is that, unlike many other semi-empirical models, it does not rely on long-term tide gauge records to statistically predict future sea levels. However, our sea level projections do not at this time include changes in land level. The numbers we supply here are for how much we can expect the water volume to rise near to each of these park units. Table E1 shows how land levels are changing at long-term tide gauges across the country. However, given that all of these park units are located far from a tide gauge and that the region is relatively geologically complex, we would not recommend using the land movement numbers from the nearest tide gauge for any of the Alaskan parks.
Storm surge is also very difficult to model for this region. Historically, many of the parks had sea ice along the coastline that helped protect these parks from storm surge. Consequently NOAA do not have SLOSH MOM models for this region. IBTrACS data (Knapp et al. 2010) show a few storm paths that have moved towards the region, but these types of storms typically do not make landfall once they move over colder waters. Alaska does hold the record for the highest intensity (lowest central pressure) storm (Duff 2015). A downgraded super typhoon, Nuri, struck Adak Island, Alaska in 2014 with recorded winds gusting up to 122 mph. It is unfortunately impossible to determine an average or peak historical storm surge without adequate tide gauge data.

Discussion

Global mean sea levels have been rising since the last glacial maximum (Lambeck and Chappell 2001, Clark and Mix 2002, Lambeck et al. 2014). Church and White (2006) estimated that twentieth century global sea levels rose at a rate of approximately 1.7 mm/yr, although this rate accelerated over the later part of the century. Slangan et al. (2016) found that the release of anthropogenic greenhouse gases has been the primary driver of global sea level change since 1970 as the rate of sea level rise has increased over time (Table 1). Satellite altimetry data shows that present-day global relative sea levels are increasing at approximately 3.3 mm/yr (Cazenave et al. 2014, Fasullo et al. 2016).

The IPCC (2013) expects this rate will increase and predicts global average sea levels to increase by 0.40–0.63 m (RCP2.6–8.5) by 2100. We used regional sea level projections from the IPCC (2013) generated for 2050 and 2100 in combination with our own downscaled projections for 2030 to estimate how much sea level rise 118 coastal national park units could experience in the future. Our are projections are based on the new representative concentration pathways (Meinshausen et al. 2011, Figure 14) and use a process based model approach.

Figure 14: Radiative forcing for each of the Representative Concentration Pathways (RCPs). RCPs replace the IPCC SRES scenarios. Note how RCP4.5 (yellow line) projections are higher than RCP6.0 (gray line) in the early part of this century. Source: Meinshausen et al. 2011.
There are numerous academic articles that use mostly semi-empirical models (Rahmstorf 2007) to estimate sea level rise for a number of regions across the U.S. The IPCC (2013) lists a number of semi-empirical sea level estimates, all of which create estimates of future sea level that are higher than the IPCC (2013) approach. The differences to these approaches can be attributed to a number of factors. For example, some of the older papers may have higher sea level estimates because they are based on the older IPCC SCRES scenarios (e.g. Vermeer and Rahmstorf 2009, Grinsted et al. 2010, Jevrejeva et al. 2010). Other papers may augment their sea level projections with “expert elicitation” where experts are polled on how much they think sea level (or a related factor) could rise in the future (e.g. Bamber and Aspinall 2013, Jevrejeva et al. 2014, Horton et al. 2014). Others have published articles criticizing the IPCC sea level estimates as being too conservative or underestimating rates of future sea level change (e.g. Kerr 2013, Horton et al. 2014). These criticisms were addressed by Church et al. (2013) and so they will not be discussed in detail here. Recent analyses by Clark et al. (2015) further supports the findings of the IPCC.

A key strength of these methods has been that this research applies a unified approach to identify how sea level change will impact all coastal park units across the National Park System, rather than relying on sea level data generated for specific regions. Our analyses revealed that the National Capital Region is projected to be the region to experience then greatest increase in sea level (not taking into account changes in land level). This rise will impact each of the region’s units in different ways depending on the elevation of the individual unit, but it could be catastrophic if combined with a storm surge from a storm such as the category 2 hurricane in 1878.

At the individual park level IPCC projections reveal the sea level along the coastline adjacent to Wright Brothers National Memorial could rise up 0.82 m (RCP8.5) by 2100, which could lead to significant flooding if combined with a storm surge. The Southeast Region as a whole is generally susceptible to inundation and flooding due to its low-lying nature in many places, particularly in the Cape Hatteras/Cape Lookout National Seashores region. Our sea level rise maps highlight how much all of these park units will be impacted.

However these estimates do not factor in changing land levels. We are expecting the latest state-of-the-art land level estimates to be released by NASA in 2017. In the meantime we can roughly estimate relative sea level change for a small number of parks based on current rates of subsidence gathered from nearby long-term tide gauge data. We expect Jean Lafitte National Historical Park and Preserve to have the greatest relative sea level increase based on the current rate of land movement. Our sea level projections agree with current sea level trends that the southeast Alaska region is experiencing the least amount of sea level rise of anywhere in the National Park System.

Sallenger et al. (2012) discussed how storm surge combined with sea level rise could create a 1000-km long “hotspot” along the North Atlantic coast from Cape Cod, Massachusetts to Cape Hatteras, North Carolina. Our projections also found that to be the case. We mapped future inundation caused by sea level change combined with flooding caused by a storm measuring one storm category higher than historical for each park unit, assuming an intensification of future storm surge (Webster 2005, Mingfang 2015). We found that almost all of the coastal park units would be flooded under these conditions.
It is unknown exactly to what degree future storm surge will impact the Alaskan park units. Storm accurate long-term (>30 years) surge data do not exist for the Alaska region. Even if such data did exist it would be not be analogous to future conditions in the regions as sea ice that had previously protected the shores for many of the western Alaska park units melts to reveal an easily erodible coastline (Frey et al. 2015). The warming of ocean waters in the Gulf of Alaska and Pacific Ocean could also make it more conducive for more storms like Typhoon Nuri to travel north without losing as energy as they once did.

The Pacific West Region shows a lot of variability among parks. A recent report by Golden Gate National Recreation Area (2016) goes into detail regarding what some of these park units are doing to plan for climate change. The National Research Council report for California, Washington, and Oregon (2012) has been cited frequently as a resource on sea level rise in the region, but it does not cover the entire administrative region that is managed by the Pacific West Region. War in Pacific National Historical Park in Guam ranks first as having the highest projected sea level rise amongst the units administered by the Pacific West Region.

Island park units in general are especially exposed to the impacts of sea level change and storm surge. Many of the barrier island parks, such as Fire Island National Seashore, Assateague National Seashore, Palo Alto Battlefield National Historical Park, Gulf Islands National Seashore and Cape Hatteras National Seashore are all projected to experience sea level rises over 0.69 m by 2100 (RCP8.5). This sea level rise combined with storm surge could be especially difficult for isolated island park units, such as the Caribbean park units, National Park of American Samoa, and War in Pacific National Historical Park where access to aid in the event of a natural disaster may not be immediately available.

Conclusions

Projections of sea level change and storm surge due to anthropogenic climate change in 118 coastal park units administered by the National Park Service are presented in this report. Historical storm surge data showed the Southeast Region to have experienced the most intense hurricanes, which could lead to even greater storm surges in the future if storms become stronger (Webster 2005, Mingfang 2015). Sea level rise is projected to generally be greatest in the National Capital Region, although some low-lying parks, such as Everglades National Park and park units in the Outer Banks of North Carolina and Gulf Coast will continue to be challenged by this issue.

Sea level and storm surge will vary geographically, resulting in unique challenges for adaptation and management. It is important to acknowledge that sea level change will impact some parts of Alaska differently to the rest of the country. Northwest Alaska can expect relative sea levels to increase over time, while southeast Alaska relative sea levels will likely continue to decrease over the first part of this century followed by an increase in relative sea level by the end of the century.
This project is an important first step in assessing how changes in sea level and storm surge due to anthropogenic climate change will impact our national park units. By combining projected sea level with storm surge data we can start to examine how these two separate variables can exacerbate the impact of each other over time. It is clear that more research can be done on these complex issues to assess how these changes will impact individual parks as well as the wider regions. Looking ahead, these data have applications for a number of future projects related to both natural and cultural resources as well as the planning and management of infrastructure.

Appendix C

Frequently Asked Questions

Q. How were the parks in this project selected?
A. Parks were selected after consultation with regional managers. Regional managers were given a list of parks that authors considered to be vulnerable to sea level change and/or storm surge. This list was vetted by regional managers and their staff who added or subtracted park names based on their knowledge of the region.

Q. Who originally identified which park units should be used in this study?
A. The initial list of parks was approved by the following regional managers: Northeast Region, Amanda Babson (signed 11/27/13); Southeast Region, Shawn Benge (signed 11/14/13); National Capital Region, Perry Wheelock (signed 3/17/14); Intermountain Region, Patrick Malone signed on behalf of Tammy Whittington (signed 11/13/13); Pacific Region, Jay Goldsmith (signed 11/26/13); Alaska Region, Robert Winfree (signed 11/15/13).

Q. What’s the timeline of this project?
A. This is the culmination of a three-year project that was proposed in February 2012. Initial Fiscal year of funding was 2013.

Q. Where did you use data used by Tebaldi et al. (2012)?
A. NOAA’s Sea Lake and Overland Surge from Hurricanes (SLOSH) model does not include storm surge predictions for all of the parks used in this study. We used data from Tebaldi et al. (2012) where reasonable to help plug some of these gaps in our data network for park units in California, Oregon, Washington, and southern Alaska.

Q. Why don’t all of the parks have storm surge maps?
A. Unfortunately some parks do not have enough data to complete a storm surge map. These were parks that were not modeled by NOAA’s SLOSH MOM model or near any of the tide gauges used by Tebaldi et al. (2012). The following parks used Tebaldi et al. (2012) data: Klondike Gold Rush National Historical Park, Lewis and Clark National Historical Park, Olympic National Park, Port Chicago Naval Magazine National Scenic Trail, Point Reyes National Seashore, Redwood National Park, San Francisco Maritime National Historical Park, San Juan Island National Historical Park, and Santa Monica Mountains National Recreation Area.

Q. My park only has storm surge maps covering a few Saffir-Simpson categories. Why is that?
A. Some parks, particularly those in the Northeast Region, were not modeled by NOAA for the full range of Saffir-Simpson storm scenarios. This is because it is considered very unlikely that a Saffir-Simpson category 4 or 5 hurricane would be able to sustain itself into that region.
Q. Why are the storm surge maps in NAVD88?

That is the default datum for SLOSH data. This was a decision made by NOAA.

Q. What are the effects of NAVD88 on projections for some parks?

The North American Vertical Datum of 1988 (NAVD88) is a datum that is commonly used in North America. It uses a fixed value for the height of the sea level. While this is a popular datum for mapping, it has the limitation that it is based on the tidal benchmark for Rimouski, Canada. As you move further away from this benchmark you can expect actual sea level to differ from the reference benchmark. For locations such as California this can result in a significant difference between observed mean sea level and NAVD88. Your natural resource or GIS specialist will likely have further information about your specific location. Alternatively you can look up the differences in your region by checking the datum information for your nearest tide gauge station: https://tidesandcurrents.noaa.gov/stations.html?type=Datums

Q. Which sea level change or storm surge scenario would you recommend I use?

All parks are different, as are all projects. Your choice of scenario may depend on many different factors. The NPS has not yet released any guidance on which climate change scenarios to use for planning. We would recommend you contact the appropriate project lead, natural or cultural resource manager, or someone from the Climate Change Response Program for further guidance depending on your situation.

Q. How accurate are these numbers?

A. The accuracy of these data varies depending on the data source. SLOSH data has +/- 20% accuracy, although this is discussed in greater detail by Glahn et al. 2009. Further information about storm surge data generated by Tebaldi et al. can be found in Tebaldi et al. (2012). The standard error of the IPCC is explained in greater detail in the chapter 13 supplementary material in AR5 (IPCC 2013).

Q. We have had higher/lower storm surge numbers in the past. Why?

A. The numbers given here are meant to represent an average storm surge number. As described above there is likely to be some deviation around that number. Certain periods are also likely to result in higher than average storm surges. For example, El Niño and La Niña years will impact sea level. Likewise, changes in the North Atlantic Oscillation and Pacific Decadal Oscillation will also affect ocean conditions. This must be taken into account when using these numbers. All of these factors vary temporally and geographically, so contact your natural resource manager if you are unsure how this could impact your particular park unit.

Q. What other factors should I consider when looking at these numbers?

A. These projections do not include the impact of man-made structures, such as levees and dams. They also do not take into account how smaller features, such as dune systems or vegetation changes...
could impact coastal flooding. There are many meso- and micro-scale factors that need to be taken into account such as differences in topography, the presence/absence of any wetlands etc. It should also be expected that as sea levels change, areas of the shoreline will change accordingly, particularly due to erosion and accretion.

Q. Why don’t you recommend that I add storm surge numbers on top of the sea level change numbers?

A. Sea level change is expected to have a significant impact on the geomorphology of the coastline. Changing water levels will lead to areas of greater erosion in some areas as well as increasing accretion in other places. Permanent inundation will change the way waves propagate within a basin in the future. As sea level changes, the fluid dynamics of a particular region will also change. This is not something NOAA takes into account in their SLOSH model.

Q. Where can I get more information about the sea level models used in this study?

Q. Where can I get more information about the NOAA SLOSH model?

A. http://www.nhc.noaa.gov/surge/slosh.php

Q. So, based on your maps, can I assume that my location will stay dry in the future?

A. No. As explained above, these numbers are accurate within a certain range. Also, these maps are based on “bath tub” models where water is simulated as rising over a static surface. In reality, your coastline will change in response to storms and other coastal dynamics. These numbers are intended for guidance only.

Q. Why do you use the period 1986–2005 as a baseline for your sea level rise projections?

A. We are following the standard approach used by the IPCC, USACE, and much of the academic literature. If you would like your estimate to start from a specific year you can do one of two things: 1) subtract the observed rate of sea level rise since 1992 for your location, or 2) contact Rebecca Beavers for assistance. It may be possible to downscale projections further to estimate the amount of rise the models estimate to have taken place between the baseline and whichever year you choose. We must caution that if you follow option 1 you will be introducing some inaccuracy to sea level projections, especially if you use data from a tide gauge that is not close to your location.

Q. The SLOSH/IPCC projections seem lower/higher than X source I’ve found. Why is that?

A. Projections can vary depending on a number of factors such as choice of model, approach, or the age of the study. We would recommend that you speak to a climate specialist when choosing between sources.

Q. What are other impacts from sea-level rise that parks should consider?
A. Impacts from sea-level rise could include, but are not limited to, destroyed cultural resources, damage to above ground infrastructure, difficulty accessing buried infrastructure, increased groundwater intrusion, altered groundwater salinity, diminished space for recreational activities (possibly leading to conflict between different recreational users), and the complete loss or migration of certain coastal ecosystems.

Waysides

The following pages show the final designs for waysides that were installed in parks as part of the funding for this project. Gulf Islands National Seashore received two waysides that were received in 2015. Jean Lafitte National Historical Park and Preserve and Fire Island National Seashores waysides were installed in 2016.
See Change...

The earth’s climate is changing, raising sea level and increasing the frequency of storm surges. Erosion and rising sea level change the shape and size of barrier islands and mainland shorelines along the Gulf Coast.

The roots of coastal plants slow erosion by anchoring the land. As sea level rises, increased salt content in the soil will kill the plants leaving the land exposed to more erosion. In many places, the amount of dry land is decreasing at a significant rate.

The Gulf Coast draws millions of visitors to relax in the bright sun, play in the crystal blue surf, explore the snow white beaches, and watch for wildlife. Yet, this dry land, at the edge of rising waters, could be claimed by the Gulf of Mexico forever.

Gulf Islands National Seashore is investing in energy efficient equipment and seeking new sustainable solutions to help keep these shores from disappearing beneath the rising sea.

Each year, erosion, storms, coastal development, and rising sea level shrink the nesting beach habitat of sea turtles. When a female sea turtle is ready to lay her eggs, she will try to return to the same sandy beach every two to three years. Will her nesting home still be here?

Please join the National Park Service in protecting these beaches, so that you and your children may watch her hatchlings return to lay their eggs.

This road at Fort Pickens gets overwashed with storm waves. As the sea level rises, these events are becoming more common.

Gulf Islands National Seashore is investing in energy efficient equipment and seeking new sustainable solutions to help keep these shores from disappearing beneath the rising sea.

Fighting the Rising Sea

Each year, erosion, storms, shipping channels, and rising sea level are changing the boundaries of the barrier islands. The National Park Service and Corps of Engineers work together on renourishment projects to rebuild the coastline around historic Fort Massachusetts. The fort is often battered by waves, putting the structure in jeopardy.

Please join the National Park Service in protecting our seashore, so that you and your children may continue to enjoy its historic places.
Sinking Land, Rising Water

This is the Barataria Basin, built of soil washed to this area by the Mississippi River. This soil is still compacting and sinking, a process called subsidence. Most of the Barataria Preserve is less than two feet above sea level, and its subsidence rate is nearly half an inch a year.

Meanwhile, glaciers and polar ice sheets are melting and our warming climate is heating oceans everywhere, making their waters expand just like water does when you heat it on the stove. Everywhere on the planet, the oceans are a little higher every day.

The combination of the Barataria Basin’s sinking land and global sea level rise means that the ocean is creeping in faster here than almost anywhere else in North America.

- Floods are becoming more frequent and lasting longer
- Coastal wetlands are disappearing as land sinks and water rises
- Less land is available to buffer Gulf of Mexico storms
- Storm and flooding threats to homes, communities, and infrastructure like highways, ports, and energy facilities are increasing
- Salt water from the Gulf is moving into freshwater wetlands, killing the plants that hold the land together
- Death of plants, animals, and microbes that cannot tolerate increased flooding or salt water

The photo shows two feet of flooding on Barataria Boulevard after Hurricane Isaac in August 2012. The map shows predicted consequences of 18 inches of sea level rise in the preserve. Blue areas would be flooded and brown areas would remain land.
See Change In A Changing Climate

Natural landscape change can be nearly imperceptible on a barrier island, as the wind and waves gradually shape the shoreline, beach, and dunes. Natural changes can also be obvious and happen quickly during storms like hurricanes and nor’easters. Looking ahead, storms will have a greater impact on Fire Island due to climate change.

When we burn fossil fuels, carbon dioxide is released into the atmosphere and acts like a heat trapping blanket around our planet. Heat that would normally escape from the atmosphere is retained, warming the Earth, and changing climate patterns. As ocean waters warm and ice on land melts, sea level rises and impacts Fire Island and coastlines all over the world. The future of this barrier island is in jeopardy due to these human-induced climate change effects.

Fire Island protects mainland Long Island against storms and is a stunning setting for recreation, education, and inspiration. It also provides critical habitat for plants and wildlife. We must do what we can to protect this special place. By using renewable energy sources and reducing our dependence on fossil fuels, we can take steps today to preserve barrier island systems and processes, and help build natural resilience to future storms and sea-level rise.

Storm Stories

On October 29, 2012, Hurricane Sandy struck Fire Island National Seashore and changed the lay of the land. During the storm high water and large waves scoured sand from the beach and dunes, moved sand across the width of the island, and carved the beach, pictured here, through the barrier island. The storm was the strongest in recorded history to make landfall in this region.

To learn more about how climate change is impacting the Seashore, please visit www.nps.gov/fis/learn/climatechange.htm

1 Number of years used by the USACE to calculate sea level change (source: [http://www.corpsclimate.us/ccaceslcurves(superseded).cfm](http://www.corpsclimate.us/ccaceslcurves(superseded).cfm))

2 It is not recommended that you use this tide gauge data to determine land level for this park. The boundary is located either too far away or on a different land mass to where the nearest tide gauge is, which increases the inaccuracy of this data. It is strongly recommended that you wait for the forthcoming NASA report on land level (Nerem in prep).

3 *The park boundary stretches over either large or multiple areas. More than one tide gauge record is appropriate for this park.
Table E2. Sea level rise numbers by NPS unit. Results are sorted by region. Values are reported in meters. See table footnotes for further details.

1 Parks that do not have shoreline. These numbers are for the nearest shoreline to the park.

2 Parks that are likely to be significantly impacted by changes in land level that could result decreasing relative sea level in the short term followed by increased relative sea level by the end of the century. Refer to section methods for more information.
1 ‡No data was available for this scenario. Data from an adjacent cell was used in lieu.

2 §Parks that cover two or more cells. Data were averaged between these parks based on percentage of shoreline in each cell.

3 Adjacent cells were used in cases where boundaries crossed into null data cells.
Table E3. IBTrACS data (Knapp et al. 2010) was used to identify the highest recorded storm track to have passed within 10 miles of each of the park units.

NPS XXXXXX, September 2016
12 Re_ REQUEST_ peer review manager for sea level_....pdf
Hi Rebecca,

If you handle this like you've done in the past (i.e., you do 99% of the work ...) then I'd be happy to read through the materials and do that last 1%.

Cheers,

johng

On Fri, Sep 2, 2016 at 2:52 PM, Beavers, Rebecca <rebecca_beavers@nps.gov> wrote:

Hi John:

Maria Caffrey, Patrick, Amanda, and I met this week; we are the non-external component of the sea level/storm surge project's science team. In 1-2 weeks, Maria Caffrey will submit a report and GIS data for NPS NRSS review. This will likely be published as 2 items: a NRR and data series.

We are at the point that we need a CCRP peer review manager (other than one of us). I highly recommended you, and Cat gave her OK to ask you via correspondence w/ Patrick ;-) 

Since you have done this role with me before, you know I will help as appropriate to reduce the time required by you. We also have Amanda stepping up to help, too.

Will you serve as the peer review manager for these 2 items: a NRR and data series?

Thank you!

-rebecca

On Mon, Sep 12, 2016 at 10:43 AM, Rob Thieler <rthieler@usgs.gov> wrote:

Maria,

Sorry to have missed the call. The invite came while I was (b) (6), and when we came back (b) (6), Suffice to say I've been running to catch up. But unfortunately this request is one where the train leaves me behind.

I gave the report a really, really quick glance over. A couple things that you may want to add:
more discussion of a) why the IPCC SLR projections are used (beyond just the process model rationale, e.g., are they more spatially comprehensive than other options), and b) how these projections and their uncertainties compare to more recent work (e.g., Kopp et al. 2014 Earth’s Future; 2016 PNAS), as well as the projections used in the third National Climate Assessment. Much as I use and admire the work of IPCC, their projections weren’t out a week before people started looking for the next thing. (For better or worse, almost seems like SLR projections have gone into 24-hour news cycle mode.) Obviously you have to choose something, but it bears explaining and comparing what you chose in a bit more depth.

comparison of the storm MEOW/MOM approach to recent extreme water level work, e.g., Sweet and Park 2014 Earth’s Future; Hall et al. 2016 for DOD https://www.serdp-estcp.org/News-and-Events/News-Announcements/Program-News/DoD-Report-on-Regional-Sea-Level-Scenarios. Also, how this compares to similar work by UCS (http://www.ucsusa.org/sites/default/files/attach/2016/07/us-military-on-front-lines-of-rising-seas_all-materials.pdf). Point being that there are an increasing number of these studies and there is increasing potential for brand, data, and most importantly, conclusion confusion (esp in situations where you have a studied military installation near/next to a studied NPS unit).

Hope this little bit helps. Holler if you want suggestions for external reviewers. But authors of the aforementioned reports would be a good place to start.

Best,
-rt

Subject: Sea level and storm surge project draft report

Hi Rob,

Sorry you couldn't make our call this week. The good news is that I've put together a draft of my final report. I was wondering if you have time to look it over? Patrick has asked that I send a copy of this to each science team member for your initial review before I send it out for
wider review by the regions and external reviewers. We are also sending the GIS data out for separate review by GIS specialists. We are planning on issuing the GIS data in a separate publication.

So sorry for the short notice. Would it be possible for you to look it over and get back to me by 9/16? If not, I can always add you as a reviewer when it goes out for wider review, but I thought you might want to check it out before I send it to too many people.

I have attached the report along with an excel file for your comments. It will be easier to compile the comments if they are in a table format rather using four versions of track changes. Thanks for your help on this.

Have a great labor day weekend.

14 SLR statement; IUCN; Patrick’s brief.pdf
Maria and Rebecca,

Very nice visiting with you about the report and associated data. From a very selfish perspective, your work is going to be extremely useful to me and others in CCRP so full steam ahead! And more broadly (and perhaps more immediately), the information is going to be even more helpful to people in facilities and operations. So I'll do everything I can to help you polish this and push it out the door.

On SLR: I also agree totally with what Patrick put in his brief, but he completely failed to address the concern I have, which is that IPCC has very explicit requirements about the information and data that it allows to be considered in e.g. estimating SLR or other climate increases. My concern is that we are very rapidly increasing our knowledge of ice and ocean dynamics, both through the analysis of existing observations, and we are now observing changes and dynamics that were not apparent at the time the last IPCC projections were produced. Attached are a couple papers that support my (perhaps incorrect) impression that newer studies are mostly supporting SLR projections greater than IPCC. (BTW, Boetsch et al. has an exceptionally nice explanation of why bay surges will increase even more than SLR. I had absolutely no appreciation or understanding of this, and even I could present it to park staff after reading the report).

I hoped Patrick would address the differences between IPCC and other (mostly newer) projections. I'm not so much interested in how IPCC did their projections, but really would like an expert assessment or synthesis of the suite of SLR projections and whether the newer projections of greater SLR rates are credible and broadly supported by the community of scientists with suitable expertise.

And.. here's the URL for the partly-laid-out version, and below the statement that I made and that I'm wondering if you think is OK/correct/could be improved.

URL for guide: http://www.georgewright.org/iucn_cc_bpg_arc

Statement (PAs = protected areas)

Sea level rise is important for many PAs, and it is thus may be an important variable to include in climate scenarios. The IPCC Working Group 1 report (2013, Chapter 13) includes regional-scale sea level rise projections. Some recent analyses have estimated greater rates of sea level rise than those reported by IPCC, particularly studies with new information of ice sheet dynamics (DeConto et al., 2016). Both high and low estimates can be used in scenarios to represent the range of projections for sea level increases.

Cheers,

johng
Hi John,

Here is the file I mentioned in our meeting today.

Cheers,

Contribution of Antarctica to past and future sea-level rise

Robert M. DeConto1 & David Pollard2

Polar temperatures over the last several million years have, at times, been slightly warmer than today, yet global mean sea level has been 6–9 metres higher as recently as the Last Interglacial (130,000 to 115,000 years ago) and possibly higher during the Pliocene epoch (about three million years ago). In both cases the Antarctic ice sheet has been implicated as the primary contributor, hinting at its future vulnerability. Here we use a model coupling ice sheet and climate dynamics—including previously underappreciated processes linking atmospheric warming with hydrofracturing of buttressing ice shelves and structural collapse of marine-terminating ice cliffs—that is calibrated against Pliocene and Last Interglacial sea-level estimates and applied to future greenhouse gas emission scenarios. Antarctica has the potential to contribute more than a metre of sea-level rise by 2100 and more than 15 metres by 2500, if emissions continue unabated. In this case atmospheric warming will soon become the dominant driver of ice loss, but prolonged ocean warming will delay its recovery for thousands of years.

Reconstructions of the global mean sea level (GMSL) during past warm climate intervals including the Pliocene (about three million years ago) and late Pleistocene interglacials imply that the Antarctic ice sheet has considerable sensitivity, Pliocene atmospheric CO₂ concentrations were comparable to today’s (~400 parts per million by volume, p.p.m.v.), but some sea-level reconstructions are 10–30 m higher. In addition to the loss of the Greenland Ice Sheet and the West Antarctic Ice Sheet (WAIS), these high sea levels require the partial retreat of the East Antarctic Ice Sheet (EAIS), which is further supported by sedimentary evidence from the Antarctic margin. During the more recent Last Interglacial (LIG, 130,000 to 115,000 years ago), GMSL was 6–9.3 m higher than it is today, at a time when atmospheric CO₂ concentrations were below 280 p.p.m.v. (ref. 9) and global mean temperatures were only about 0–2°C warmer. This requires a substantial sea-level contribution from Antarctica of 3.6–7.4 m in addition to an estimated 1.5–2 m from Greenland11,12 and around 0.4 m from ocean steric effects. For both the Pliocene and the LIG, it is difficult to obtain the inferred sea-level values from ice-sheet models used in future projections.

Marine ice sheet and ice cliff instabilities

Much of the WAIS sits on bedrock hundreds to thousands of metres below sea level (Fig. 1a). Today, extensive floating ice shelves in the Ross and Weddell Seas, and smaller ice shelves and ice tongues in the Amundsen and Bellingshausen seas (Fig. 1b) provide buttressing that impedes the seaward flow of ice and stabilizes marine grounding zones (Fig. 2a). Despite their thickness (typically about 1 km near the grounding line to a few hundred metres at the calving front), a warming ocean has the potential to quickly erode ice shelves from below, at rates exceeding 10 m yr⁻¹°C⁻¹ (ref. 14). Ice-shelf thinning and reduced backstress enhance seaward ice flow, grounding-zone thinning, and retreat (Fig. 2b). Because the flux of ice across the grounding line increases strongly as a function of its thickness, initial retreat onto a reverse-sloping bed (where the bed deepens and the ice thickens upstream) can trigger a runaway Marine Ice Sheet Instability (MISI; Fig. 2c)15–17. Many WAIS grounding zones sit preciparously on the edge of such reverse-sloped beds, but the EAIS also contains deep subglacial basins with reverse-sloping, marine-terminating outlet troughs up to 1,500 m deep (Fig. 1). The ice above floatation in these East Antarctic basins is much thicker than in West Antarctica, with the potential to raise GMSL by around 20 m if the ice in those basins is lost13. Importantly, previous ice-sheet simulations accounting for migrating grounding lines and MISI dynamics have shown the potential for repeated WAIS retreats and readvances over the past few million years15, but could only account for GMSL rises of about 1 m during the LIG and 7 m in the warm Pliocene, which are substantially smaller than geological estimates.

So far, the potential for MISI to cause ice-sheet retreat has focused on the role of ocean-driven melting of buttressing ice shelves from below16,18–20. However, it is often overlooked that the major ice shelves in the Ross and Weddell seas and the many smaller shelves and ice tongues buttressing outlet glaciers are also vulnerable to atmospheric warming. Today, summer temperatures approach or just exceed 0°C on many shelves21, and their flat surfaces near sea level mean that little atmospheric warming would be needed to dramatically increase the areal extent of surface melting and summer rainfall.

Meltwater on ice-shelf surfaces causes thinning if it percolates through the shelf to the ocean. If refreezing occurs, the ice is warmed, reducing its viscosity and speeding its flow. The presence of rain and meltwater can also influence crevassing and calving rates (hydrofracturing) as witnessed on the Antarctic Peninsula’s Larson B ice shelf during its sudden break-up in 200224. Similar dynamics could have affected the ice sheet during ancient warm intervals25, and given enough future warming, could eventually affect many ice shelves and ice tongues, including the major buttressing shelves in the Ross and Weddell seas.

Another physical mechanism previously underappreciated at the ice-sheet scale involves the mechanical collapse of ice cliffs in places where marine-terminating ice margins approach 1 km in thickness, with >90 m of vertical exposure above sea level26. Today, most Antarctic outlet glaciers with deep beds approaching a water depth of 1 km are protected by buttressing ice shelves, with gently sloping surfaces at the grounding line (Fig. 2d). However, given enough atmospheric warming above or ocean warming below (Fig. 2e), ice-shelf retreat can outpace its dynamically accelerated seaward flow as buttressing is lost and...
in the few places where such conditions exist today (the Helheim and Jakobsavn glaciers on Greenland and the Crane Glacier on the Antarctic Peninsula), hinting that a Marine Ice Cliff Instability (MICI) in addition to MISI could be an important contributor to past and future ice-sheet retreat.

Our three-dimensional ice sheet–ice shelf model\(^\text{25-27}\) (Methods) predicts the evolution of continental ice thickness and temperature as a function of ice flow (deformation and sliding) and changes in mass balance via precipitation, runoff, basal melt, oceanic melt under ice shelves and on vertical ice faces, calving, and tidewater ice-cliff failure. The model captures MISI (Fig. 2a–c) by accounting for migrating grounding lines and the buttressing effects of ice shelves with pinning points and side-shear. To capture the dynamics of MOCI (Fig. 2d–f), new physical treatments of surface-melt and rainwater-enhanced calving (hydrofracturing) and grounding-line ice-cliff dynamics have been added\(^\text{26}\). Including these processes was found to increase the model's contribution to Pliocene GMSL from \(+7\) m (ref. \text{18}) to \(+17\) m (ref. \text{25}). The model formulation used here is similar to that described in ref. \text{25}, but with improvements in the treatment of calving, thermodynamics, and climate–ice–ocean coupling (Methods).

### The Antarctic Ice Sheet during the LIG

Summer air temperatures in the RCM are slightly warmer at \(116\) kyr ago than \(128\) kyr ago, but remain below freezing in both cases, with little to no surface melt (Extended Data Fig. 2). As a result, substantial oceanic warming \(>4^\circ\text{C}\) is required to initiate WAIS retreat at \(128\) kyr ago, which occurs on account of the ocean-melt threshold is reached in the stability of the Thwaites grounding line (Extended Data Fig. 2a). Allowing two-way coupling between the RCM and the ice-sheet model

---

**Figure 1** | Antarctic sub-glacial topography and ice shelf features. a, Bedrock elevations\(^\text{13}\) interpolated onto the 10-km polar stereographic ice-sheet model grid and used in Pliocene, LIG, and future ice-sheet simulations. b, Model surface ice speeds and grounding lines (black lines) show the location of major ice streams, outlet glaciers, and buttressing ice shelves (seaward of grounding lines) relative to the underlying topography in a. Features and place names mentioned in the text are also shown.

**AS**, Amundsen Sea; **BS**, Bellingshausen Sea; **WDIC**, WAIS Divide Ice Core. The locations of the Pine Island, Thwaites, Ninnis, Mertz, Totten, and Recovery glaciers are shown. Model ice speeds (b) are shown after equilibration with a modern atmospheric and ocean climatology (see Methods).
Still requires >4 °C of ocean warming to produce a > 3.5 m increase in future ice response. (Methods) captures dynamical atmospheric feedbacks as the ice seaward ice flux, backing the grounding line onto reverse-sloping bedrock. and LIG sea level are in much better agreement with geological estimates of the WAIS satisfies the presence of ice> 70 kyr ago at the bottom of the Earth 128 kyr ago. The ocean-driven continental warming at 128 kyr ago agrees with ice core records and supports a Southern Ocean control on the timing of ice-sheet retreat possibly through Northern Hemisphere influences on the ocean meridional overturning circulation.

Alternative simulations (Fig. 3) use time-evolving atmospheric and oceanic climatologies (Methods) based on marine and ice-core proxy reconstructions. These time-continuous simulations produce GMSL contributions of 6–7.5 m early in the interglacial, followed by a prolonged plateau and rapid recovery of the ice sheet beginning around 115 kyr ago. This result matches the magnitude, temporal pattern, and rate of LIG sea-level change in ref. 3. (Fig. 3a) and (f), despite the cooler orbit of the Earth 128 kyr ago. The ocean-driven continental warming at 128 kyr ago agrees with ice core records and supports a Southern Ocean control on the timing of ice-sheet retreat, possibly through Northern Hemisphere influences on the ocean meridional overturning circulation.

Combined with estimates of Greenland ice loss and ocean thermal effects, the simulated, Antarctic contributions to Pliocene and LIG sea level are in much better agreement with geological estimates than previous versions of our model, which lacked these new treatments of meltwater-enhanced calving and ice-margin dynamics, suggesting that the new model is better suited to simulations of future ice response.

Future simulations
Using the same model physics and parameter values as used in the Pliocene and LIG simulations, we apply the ice-sheet model to long-term future simulations (Methods). Here, atmospheric forcing is provided by high-resolution RCM simulations (Extended Data Fig. 4) following three extended Representative Carbon Pathway (RCP) scenarios (RCP2.6, RCP4.5 and RCP8.5). Future circum-Antarctic ocean temperatures used in our time-evolving sub-ice melt-rate calculations come from matching, high-resolution (1°) National Center for Atmospheric Research (NCAR) CCSM4 simulations (ref. 37, Extended Data Fig. 5). The simulations begin in 1950 to provide some hindcast spinup, and are run for 550 years to 2500.

The RCP scenarios (Fig. 4) produce a wide range of future Antarctic contributions to sea level, with RCP2.6 producing almost no net change by 2100, and only 20 cm by 2500. Conversely, RCP4.5 causes almost complete WAIS collapse within the next five hundred years, primarily owing to the retreat of Thwaites Glacier into the deep WAIS interior. The Siple Coast grounding zone remains stable until late in the simulation, thanks to the persistence of the buttressing Ross Ice Shelf (see Supplementary Video 2). In RCP4.5, GMSL rise is 32 cm by 2100, but subsequent retreat of the WAIS interior, followed by the fringes of the Wilkes Basin and the Totten Glacier/Law Dome sector of the Aurora Basin produces a rise of 5 m of GMSL rise by 2500.

In RCP8.5, increased precipitation causes an initial, minor gain in total ice mass (Fig. 4d), but rapidly warming summer air temperatures trigger extensive surface meltwater production and hydrofracturing of ice shelves by the middle of this century (Extended Data Fig. 4). The Larsen C is one of the first shelves to be lost, about 2055. Around the same time, major thinning and retreat of outlet glaciers commences in the Amundsen Sea Embayment, beginning with Pine Island Glacier (Fig. 4h), and along the Bellingshausen margin. Massive meltwater production on shelf surfaces, and eventually on the flanks of the ice sheet, would quickly overcome the buffering capacity of firm. In the model, the meltwater accelerates WAIS retreat via its thermomechanical influence on ice rheology (Methods) and the influence of hydrofracturing on crevassing and structural failure of the retreating margin. Antarctica contributes 77 cm of GMSL rise by 2100, and continued loss of the Ross and Weddell Sea ice shelves drives WAIS retreat from three sides simultaneously (the Amundsen, Ross, and Weddell seas), all with
reverse-sloping beds into the deep ice-sheet interior. As a result, WAIS collapses within 250 years. At the same time, steady retreat into the Wilkes and Aurora basins, where the ice above floatation is >2,000 m thick, adds substantially to the rate of sea-level rise, exceeding 4 cm yr$^{-1}$ (Fig. 4c), in the next century, which is comparable to maximum rates of sea-level rise during the last deglaciation$^\text{20}$. At 2500, GMSL rise for the RCPS.5 scenario is 12.3 m. As in our LIG simulations, atmosphere–ice sheet coupling accounting for the warming feedback associated with the retreating ice sheet adds an additional 1.3 m of GMSL to the RCPS.5 scenario (Fig. 4b).

The CCSM4 simulations providing the model's sub-ice-sheet melt rates (Extended Data Fig. 5) underestimate the penetration of warm Circum-Antarctic Deep Water into the Amundsen and Bellingshausen seas observed in recent decades$^\text{21}$. As a result, the model fails to capture recent, 21st-century thinning and grounding-line retreat along the southern Antarctic Peninsula$^\text{22}$ and the Amundsen Sea Embayment$^\text{23}$. Correcting for the ocean-model cool bias along this sector of coastline improves the position of Pine Island and Thwaites grounding lines relative to observations$^\text{24,25}$ (Fig. 4h) and increases GMSL rise by 9 cm at 2100 (mainly due to the accelerated retreat of Pine Island Glacier), but the correction has little effect on longer timescales (Extended Data Table 2). The lack of substantial ice-sheet retreat during the LIG driven by a time-evolving, proxy-based atmosphere-ocean climatology; a. Change in GMSL in LIG simulations starting at 130 kyr ago and initialized with a modern ice sheet (blue) or a bigger LGM ice sheet representing glacial conditions at the onset of the LIG (red). A probabilistic reconstruction of Antarctica's contribution to GMSL is shown in black with uncertainties (16th and 84th percentiles) as dashed lines. b, c, Ice-sheet thickness at the time of maximum retreat using modern initial conditions (b) and using glacial initial conditions (c). Ice-free land surfaces are brown. The bigger sea-level rise when initialized with the 'glacial' ice sheet is caused by deeper bed elevations and the ~3,000-yr lagged bedrock response to ice retreat$^\text{26}$, which enhances bathymetrically sensitive MISI dynamics. d. The same simulation as b without the new model physics accounting for meltwater-enhanced calving or ice-cliff failure$^\text{27}$. GMSL contributions are shown at top left.

Figure 3 | Ice-sheet simulations and Antarctic contributions to GMSL through the LIG driven by a time-evolving, proxy-based atmosphere-ocean climatology. a. The same simulation as b without the new model physics accounting for meltwater-enhanced calving or ice-cliff failure$^\text{27}$. GMSL contributions are shown at top left.

**Large Ensemble analysis**

To better utilize Pliocene and LIG geological constraints on model performance, we perform a Large Ensemble analysis (Methods) to explore the uncertainty associated with the primary parameter values controlling (1) relationships between ocean temperature and sub-ice-shelf melt rates, (2) hydrofracturing (crevasse penetration in relation to surface liquid water supply), and (3) maximum rates of marine-terminating ice-cliff failure. The combination of Pliocene and LIG sea-level targets is ideal, because Pliocene retreat is dominated by processes associated with (2) and (3), while the LIG is dominated by process (1).

Both Pliocene and LIG ensembles are run with combinations of widely ranging parameter values associated with the three processes, and the combinations are scored by their ability to simulate target ranges of Pliocene and LIG Antarctic sea-level contributions (Methods). The filtered subsets of parameter values capable of reproducing both targets are then used in ensembles of future RCP scenarios (Extended Data Table 2), providing both an envelope of possible outcomes and an estimate of the model's parametric uncertainty (Fig. 5). Importantly, the ensemble analysis supports our choice of 'default' model parameters used in the nominal Pliocene, LIG, and future simulations (Fig. 4, Extended Data Table 2). The lack of substantial ice-sheet retreat in the optimistic RCP2.6 scenario remains unchanged, but the Large Ensemble analysis substantially increases our RCP4.5 and RCP8.5 2100 sea-level projections to 49 ± 20 cm and 105 ± 30 cm, if higher (>10 m) instead of >5 m) Pliocene sea-level targets are used. Adding the ocean temperature correction in the Amundsen and Bellingshausen seas (Fig. 4d and h) further increases the 2100 projections in RCP2.6, RCP4.5 and RCP8.5 to 16 ± 16 cm, 58 ± 28 cm and 114 ± 36 cm, respectively (see Methods and Extended Data Tables 1 and 2).
Figure 4 | Future ice-sheet simulations and Antarctic contributions to GMSL from 1950 to 2500 driven by a high-resolution atmospheric model and 1° NCAR CCSM4 ocean temperatures. a, Equivalent CO₂ forcing applied to the simulations, following the RCP emission scenarios in ref. 36, except limited to 8 × PAL (preindustrial atmospheric level, where 1 PAL = 280 p.p.m.v.). b, Antarctic contribution to GMSL. c, Rate of sea-level rise and approximate timing of major retreat and thinning in the Antarctic Peninsula (AP), Amundsen Sea Embayment (ASE) outlet glaciers, AS–BS, Amundsen Sea–Bellingshausen Sea; the Totten (T), Siple Coast (SC) and Weddell Sea (WS) grounding zones, the deep Thwaites Glacier basin (TG), interior WAIS, the Recovery Glacier, and the deep EAIS basins (Wilkes and Aurora). d, Antarctic contribution to GMSL over the next 100 years for RCP8.5 with and without a +3°C adjustment in ocean model temperatures in the Amundsen and Bellingshausen seas as shown in Extended Data Fig. 5d. e–g, Ice-sheet snapshots at 2500 in the RCP2.6 (e), RCP4.5 (f) and RCP8.5 (g) scenarios. Ice-free land surfaces are shown in brown. h, Close-ups of the Amundsen Sea sector of WAIS in RCP8.5 with bias-corrected ocean model temperatures.
Long-term commitment to elevated sea level

Ocean warming alone may be limited in its potential to trigger massive, widespread ice loss, but the multi-millennial thermal response time of the ocean\(^{47}\) will have a profound influence on the ice sheet's recovery. In simulations run 5,000 years into the future, we conservatively assume no ocean warming beyond 2300 and simply maintain those ocean temperatures while the atmosphere cools assuming different scenarios of CO\(_2\) drawdown beginning in 2500 (Methods). For RCP8.5 and natural CO\(_2\) drawdown, GMSL continues to rise until 3500 with a peak of about 20 m, after which the warm ocean inhibits the re-advance of grounding lines into deep marine basins for thousands of years (Extended Data Fig. 7). Even in the moderate RCP4.5 scenario with rapidly declining CO\(_2\) after 2500, WAIS is unable to recover until the global ocean cools, implying a multi-millennial commitment to several metres of sea-level rise despite human-engineered CO\(_2\) drawdown.

Given uncertainties in model initial conditions, simplified hybrid ice dynamics, parameterized sub-ice melt, calving, structural ice-margin failure, and the ancient sea-level estimates used in our Large Ensemble analysis, the rates of ice loss simulated here should not be viewed as actual predictions, but rather as possible envelopes of behaviour (Fig. 5) that include processes not previously considered at the continental scale. These are among the first continental-scale simulations with model physics constrained by ancient sea-level estimates, simultaneously accounting for high-resolution atmosphere-ice sheet coupling and ocean model temperatures.

However, several important processes are lacking and should be included in future work. In particular, the model lacks two-way coupling between the ice sheet and the ocean. This is especially relevant for RCP8.5, in which >1 Sv of freshwater and icebergs would be supplied to the Southern Ocean during peak retreat (Extended Data Fig. 8). Rapid calving and ice-margin collapse also implies ice mélangé in restricted embayments that could provide buttressing and a negative feedback on retreat. The loss of ice mass would also have a strong effect on relative sea level at the margin owing to gravitational and solid-earth deformation effects\(^{48}\), which could affect MISI and MICI dynamics because of their strong dependency on bathymetry. Future simulations should include coupling with Earth models that account for these processes. Improved ancient sea-level estimates are also needed to further constrain model physics and to reduce uncertainties in future RCP scenarios (Fig. 5).

Despite these limitations, our new model physics are shown to be capable of simulating two very different ancient sea-level events: the LIG, driven primarily by ocean warming and MISI dynamics, and the warmer Pliocene, in which surface meltwater and MICI dynamics are also important. When applied to future scenarios with high greenhouse gas emissions, our palaeo-filtered model ensembles show the potential for Antarctica to contribute >1 m of GMSL rise by the end of this century, and >15 m of GMSL rise in the next 500 years. In RCP8.5, the projected onset of major ice-sheet retreat occurs sooner (about 2050), and is substantially faster (>4 cm yr\(^{-1}\) after 2100) and higher (Figs 4 and 5) than implied by other recent studies\(^{44,45,49}\). These differences are mainly due to our addition of model physics linking surface meltwater and ice dynamics via hydrofracturing of buttressing ice shelves and structural failure of marine-terminating ice cliffs. In addition, we use (1) freely evolving grounding-line dynamics that preclude the need for empirically calibrated retreat rates\(^{49}\), (2) highly resolved atmosphere and ocean model components rather than intermediate-complexity climate models\(^{49}\) or simplified climate forcing\(^{44}\), and (3) calibration based on major retreat during warm palaeoclimates rather than recent minor retreat driven by localized ocean forcing.

As in these prior studies, we also find that ocean-driven melt is an important driver of grounding-line retreat where warm water is in contact with ice shelves, but in scenarios with high greenhouse gas emissions we find that atmospheric warming soon overtakes the ocean as the dominant driver of Antarctic ice loss. Surface meltwater may lead to the ultimate demise of the major buttressing ice shelves (Supplementary Videos 8 and 9) and extensive grounding-line retreat, but it is the long thermal memory of the ocean that will inhibit the recovery of marine-based ice for thousands of years after greenhouse gas emissions are curtailed.

METHODS

Ice sheet–ice shelf model. We use an established ice-sheet model, with hybrid ice dynamics following the formulation described in ref. 27, and an internal condition on ice velocity at the grounding line\(^1\) that captures MISI (Fig. 2a–c) by accounting for migrating grounding lines and the buttressing effects of ice shelves with pinning points and side shear. Bedrock deformation under changing ice loads is modelled as an elastic lithospheric plate above local isostatic relaxation. A grid resolution of 10 km is used for all simulations, the finest resolution computationally feasible for long-term continental simulations. The model includes newly added treatments of hydrofracturing and ice cliff failure (Fig. 2d–f) described in ref. 25 and extended here. Basal sliding coefficients are determined by an inverse method\(^{21}\), iteratively matching ice-surface elevations to observations until a quasi-equilibrium is reached. In this case, inverted sliding coefficients are derived from a modern (preindustrial) surface climatology, using the same RCM used in our Pliocene, LIG, and future simulations.

In addition to the Pliocene and LIG targets highlighted here, the ice sheet–ice shelf model has been shown capable of simulating: (1) the modern ice sheet, including grounding line positions, ice thicknesses, velocities, ice streams, and ice shelves (Fig. 1b), (2) the Last Glacial Maximum (LGM) extent\(^{27}\), (3) the timing of post-LGM retreat\(^{18}\), and (4) the ability of the ice sheet to regrow to its modern extent following retreat\(^{21}\).

Calving and hydrofracturing. Calving depends on the combined penetration depths of surface and basal crevasses, relative to total ice thickness\(^{23,26,32,53}\). Crevasses depths are parameterized according to the divergence of the ice velocity field\(^2\), with an additional contribution depending on the logarithm of ice speed that crudely represents the accumulated strain history (ice damage) along a flow path\(^{13}\). Rapid calving is imposed as ice thickness falls below 200 m for unconfined embayments. The 200-m criterion is decreased in confined embayments according to \(200 \times \exp(-0.1 \times \max(0, \min(1, (r-\gamma_{40}))/20))\), where \(\gamma\) is the ‘arc to open ocean’ (in degrees), crudely representing the effects of ice mélangé in narrow seaweys. The unconfined onset thickness of 200 m was increased from its value of 150 m in ref. 25 in order to improve modern Ross and Weddell Sea calving–front locations. A similar dependence on \(\gamma\) is imposed for oceanic sub-ice shelf melt rates, as described below.

Surface crevasses are additionally deepened (hydrofractured) as they fill with liquid water, which is assumed to depend on the grid-scale runoff of surface melt and rainfall available after refreezing\(^{29,33}\). The crevase–depth dependence on surface runoff plus rainfall rate \(R\) (in metres per year) has been modified slightly for low R values. The \(R\) used in equation (R.6) of ref. 25 is changed to:

\[
0 \quad \text{for} \quad R < 1.5 \text{ m yr}^{-1}
\]

\[
4 \times 1.5 \times (R - 1.5) \quad \text{for} \quad 1.5 \text{ m yr}^{-1} < R < 3 \text{ m yr}^{-1}
\]

\[
R^2 \quad \text{for} \quad R > 3 \text{ m yr}^{-1} \quad \text{(as before)}
\]

This supposes that minimal hydrofracturing occurs for relatively small \(R\) values. The linear segment between 1.5 m yr\(^{-1}\) and 3 m yr\(^{-1}\) intersects the \(R^2\) parabola as a tangent at \(R = 3\). This modification prevents small amounts of recession in some East Antarctic basins for modern conditions, where small amounts of summer melt and rainfall occur.

Structural failure of ice cliffs. To account for structural ice-cliff failure\(^{26,54}\) (MICI in Fig. 2), a wastage rate of ice \(W\) is applied locally to the grid cell adjacent to tide-water grounding lines with no floating ice, if the required stresses at the exposed cliff face exceed the yield strength of ice. This condition depends on the subaerial cliff height at the interpolated grounding line relative to the maximum ice thickness that can be supported, modified locally to account for any meltwater–enhanced crevasse penetration (hydrofracturing), and any reductions in crevassing caused by backstress. For dry crevassing at an ice margin with no hydrofracturing, the maximum exposed cliff height is 100 m, assuming an ice yield strength of 1 MPa\(^{25,26}\). The formulation of \(W\) results in a steep ramp in wastage rates of 0–3 km yr\(^{-1}\), where exposed ice cliffs ramp from 80 m to 100 m. The maximum wastage rate of 3 km yr\(^{-1}\) used as our default is conservatively chosen, based on recent observations of the Jakobshavn Isbrae Glacier (up to \(\approx 12\) km yr\(^{-1}\)) and the Crane Glacier (\(\approx 5\) km yr\(^{-1}\)) following the loss of their ice-buttressing shelves\(^{35,37}\).

Other modifications to ice-sheet model physics. The model is modified from ref. 25 to include a more physically based parameterization of the vertical flow of surface mobile liquid water (runoff and rainfall) through moulines and other fracture systems towards the base\(^{22,23}\), which affects the vertical temperature profiles within the ice sheet. Vertical sub-grid-scale columns of liquid water are assumed to exist, through which the water freely drains while exchanging heat by conduction with the surrounding ambient ice that cools and can freeze some or all of the liquid water within the ice interior.

We use uniform parameter values everywhere: we set the fractional area of sub-grid columns to overall area to be 0.1, and the horizontal scale of drainage elements to be 10 m (\(R\) in ref. 22, used in the calculations of conductive heat exchange with ambient ice). The fractional area includes both large moulines and any downward movement of liquid water in crevasses or cracks of all scales, which would be prevalent in the future melting scenarios investigated here. Offline sensitivity tests show low sensitivity of our model behaviour to these values, but further investigation is warranted.

For reasonable numerical behaviour, the horizontal heat exchange needs to be part of the time-implicit vertical diffusive heat solution for ambient ice temperature in the main model. To avoid an iterative procedure in cases where all liquid water is frozen before reaching the bed, a time–explicit calculation of the water penetration is made first, and one of the following measures is applied in the time-implicit ice-temperature step: (1) the conductive heat exchange coefficient at all levels is reduced by a constant factor for the column, so that the liquid penetrates to the lowest layer but no further; and (2) the conductive coefficient is set to zero below the depth of furthest penetration. Both methods give very similar results in idealized single-column tests; method (1) was used for all runs here. In cases with greater surface liquid flux, there is no reduction of coefficients and some water reaches the base.

A minor bug fix is corrected in the calculation of vertical velocities within the ice (\(w\) in ref. 27), which previously did not account for the removal of ice at the base due to oceanic melting. This only affects advection of temperature in ice shelves, and has negligible effects on results.

Ice-sheet initial conditions. Ice-sheet initial conditions and basal sliding coefficients are provided by a 100-kyr inverse simulation following the methodology in ref. 51, using mass–balance forcing provided by a bias-corrected RCM climatology and modern observed ocean temperatures (described below). In the inverse procedure, basal sliding coefficients under modern grounded ice are adjusted iteratively to reduce the misfit with observed ice thickness, with grounding-line positions fixed to observed locations. The LIG simulation using ‘glacial’ initial conditions (Fig. 3) uses the same basal sliding coefficients (along with a relatively slippier value for modern ocean beds), but initialized from a previous simulation of the LGM with a prescribed, cold glacial climate representing conditions at \(\approx 20\)kyr ago. The total ice volume in the modern and glacial ice sheets is \(26.55 \times 10^6\) km\(^3\) and \(32.30 \times 10^6\) km\(^3\), respectively, equivalent to bedrock-compensated GMSL values of 56.80 m and 62.28 m.

Atmospheric coupling. Atmospheric climatologies providing surface mass–balance inputs to the ice model are provided by decadal averages of meteorological fields from the RegCM3 RCM\(^{39}\), adapted to Antarctica with a polar stereographic grid and small modifications of model physics for polar regions. The RCM uses a 40-km grid, over a generous domain spanning Antarctica and surrounding oceans, nested within the GENESIS v3 Global Climate Model\(^{60,61}\). The GCM and RCM share the same radiation code\(^62\) and orbitally dependent calculations of shortwave insolation, important for the Pliocene and LIG palaeoclimatic simulations.

Anomaly methods are used to correct a small \(< 2^\circ C\) Antarctic cold bias in the RCM:

\[
T = T_{\text{exp}} + T_{\text{obs}} - T_{\text{ctl}}
\]

\[
P = P_{\text{exp}} \times \rho_{\text{obs}} / \rho_{\text{ctl}}
\]

where \(T\) is monthly surface air temperature and \(P\) is monthly precipitation. Subscripts ‘exp’, ‘obs’ and ‘ctl’ refer to model experiment, observed modern climatology, and model modern control, respectively. A modern (1950) RCM simulation is used for the model modern control, and the ALBMAP data set\(^63\) is used for observed modern climatology.

In the climatic correction for the difference between the ice-model surface elevation and the interpolated elevation in the climate model or observational data\(^{27}\), precipitation is now corrected as well as temperature. As before, air temperature \((\text{in degrees Celsius})\) is shifted by \(\Delta T = \gamma_{\Delta z}\), where \(\gamma = -0.008 0\text{ m}^{-1}\) is the lapse rate (that is, the decrease in atmospheric temperature with respect to altitude) and \(\Delta z\) is the elevation difference. Now, precipitation \(P\) is multiplied by a Clausius–Clapeyron-like factor:

\[
P \times P_{2\Delta T/10}
\]

Rates of surface snowfall and rainfall are now consistently multiplied by a factor \(\rho_s / \rho_i = 1.1\), where \(\rho_s\) and \(\rho_i\) are the densities of liquid water and of ice respectively. This consistently converts between the units of most climate models and climatological databases (metres of liquid water equivalent per year) and the ice-model surface budget terms (metres of ice equivalent per year).

Oceanic sub-ice shelf and calving-face melt rates. Direct coupling of high-resolution ocean models and ice sheets remains challenging. For present-day simulations we use a parameterization of sub-ice shelf melt rates, similar to that
used by other model groups. The parameterization links oceanic melt rates to the nearest observed (or modelled) ocean temperatures:

\[
OM = \frac{\dot{K}gT_\text{w}}{\rho_iL_f} |T_a - T_\text{om} - T_\text{w}|
\]

where \(T_a\) is ocean temperature interpolated from the nearest point in an observational (or model) grid, \(T_\text{w}\) is the local freezing-point temperature at the depth of the ice base, and \(C_\text{w}\) is the specific heat of ocean water. The transfer factor \(K_T = 15.77 \, \text{myr}^{-1} \, \text{K}^{-1}\) results in a combined coefficient \(K_{\text{f}}\) of 0.224 \, \text{myr}^{-1} \, \text{K}^{-1}.\) The depth dependence on \(T_\text{w}\) produces higher melt rates at the grounding line, as observed, and the dependence on \(T_a - T_\text{w}\) is quadratic. Spatially coarse observational data sets and standard GCM ocean models fail to capture detailed ocean current systems below ice-shelf cavities, this approach (Extended Data Fig. 6e and f) is preferable to the ad hoc prescription of single temperatures and transfer coefficients along individual sectors of the Antarctic margin as in ref. 27.

The effects of confined geography on ocean currents are represented by reducing basal melting depending on the total arc to open ocean, \(\alpha\), representing the concavity of the coastline. The melt rate computed from ocean temperatures as above is multiplied by the factor:

\[
\max[0, \min[1, (\alpha - 20)/20]]
\]

This effect, combined with the reduction of thin-ice calving with a similar dependence on \(\alpha\) described above, allows ice to expand into interior basins during cool-climate recovery after major retreats of marine-based ice, as presumably occurred many times in West Antarctica over the last several million years.

Melting of vertical ice surfaces in direct contact with ocean water is derived from the oceanic melt rate (OM) of surrounding grid cells, but is increased by a scaling factor of 10, producing more realistic calving front positions and in better agreement with hydrographic melt rate observations and detailed modelling.

Present-day sub-ice shelf and calving-face melt rates described here use the 1° resolution World Ocean Atlas climate data (Extended Data Fig. 1). Ocean temperatures are increased uniformly by 2°C everywhere in the Southern Ocean. The resulting Antarctic contribution of 11.3 m GMSL implies >15 m GMSL rise if an additional ~5 m contribution from Greenland and the steric effects of a warm Pliocene ocean are also considered. This result is ~6 m less than in ref. 25, reflecting a reduction in the sensitivity of the model with the changes described above.

**LIG simulations.** The LIG spans a ~20-kyr interval with greenhouse-gas atmospheric mixing ratios comparable to the pre-industrial Holocene. Opportunities for Antarctic ice-sheet retreat within this interval include a peak in the duration of Antarctic summers coeval with a boreal summer insolation maximum at 128 kyr ago, and an Antarctic summer insolation maxima one half-precession cycle later at 116 kyr ago (Extended Data Fig. 2). We target these two orbital time slices because they contrast radiatively long and weak (128 kyr ago, 120 kyr ago, 120 kyr ago, and 115 kyr ago) and the ice-sheet model is run continuously from 130 kyr ago to 115 kyr ago. The pairs of air and ocean temperature perturbations applied at each 5-kyr LIG time slice are 1.97° and 1.70°, 1.41° and 1.51°, ~0.83° and 1.09°, ~1.57° and 0.31°, respectively.

The time-continuous LIG simulations are initialized from either a present-day initial ice state (Fig. 1b), or from a prior Last Glacial Maximum simulation with 5.76 × 10^6 km^3 more ice than today. The latter initial condition may better represent the ice sheet at the onset of the LIG and leads to a greater potential sea-level rise owing to the deeper bed conditions early in the deglaciation, which enhances the bathymetrically sensitive MISI dynamics.

The proxy-forced LIG simulation clearly supports a maximum Antarctic contribution to GMSL early in the interglacial period (Fig. 3). However, we note that owing to the demonstrated influence of Southern Ocean temperature on the timing of retreat and the uncertain magnitude and chronology of our imposed forcing, these results cannot definitively rule out maximum Antarctic retreat at the end of the LIG, as has also been proposed.

**Future simulations.** Because of the new ice-model physics that directly involve the atmosphere via meltwater enhancement of crevassing and calving, highly resolved atmospheric climatologies are needed at spatial resolutions beyond those of most GCMs. However, multi-century RCP simulations are computationally infeasible. To accommodate the need for long but high-resolution climatologies, the nested GCM–RCM is run to equilibrium with 1 × PAL, 2 × PAL, 4 × PAL and 8 × PAL CO₂. In the ice-sheet simulations, CO₂ follows the extended RCP greenhouse gas emissions to the year 2500, and the climate at any time is the average of the two appropriate surrounding RCM solutions, weighted according to the logarithm of the concentration of CO₂. The RCM climatologies follow total equivalent CO₂, which accounts for all radiatively active trace gases in the RCP timeseries. In RCP8.5, equivalent CO₂ forcing exceeds 8 × PAL after 2175, but it is conservatively limited here to a maximum of 8 × PAL (Fig. 4a). A 10-kyr lag is imposed in the RCM climatologies to reflect the average offset between sea surface temperatures and surface air temperatures in the equilibrated RCM (with equilibrated sea surface temperatures from the parent GCM) and the transient response of the real ocean’s mixed layer.

Ocean temperatures in the RCP scenarios are provided by high-resolution (0.5° atmosphere and 1° ocean) NCAr CCSM4 ocean model output, following the RCP2.6, RCP4.5, and RCP8.5 greenhouse gas emissions scenarios run to 2300. Ocean temperatures beyond the limit of the CCSM4 simulations at 2300 are conservatively maintained at their 2300 values. As with the World Ocean Atlas, water temperatures at 400-m depth (between ocean model z-levels 30 and 31) are used in the parameterization of oceanic sub-ice melt (oceanic melt rate) described above. The CCSM4 underestimates the wind-driven warming of Antarctic Shelf Bottom Water in the Amundsen and Bellingshausen seas associated with recent increases in melt rates and grounding-line retreat. To account for this, additional warming is added to the Amundsen and Bellingshausen sectors of the continental margin. We find the addition of 3°C to the CCSM4 ocean temperatures increases melt rates to 25–30 m yr⁻¹ (Extended Data Fig. 5f). While still less than observed, this substantially improves grounding-line positions in the Amundsen Sea (Pine Island Glacier in particular) from 1950 to 2015. When applied to RCP4.5 and RCP8.5, the ocean-bias correction accelerates twenty-first-century WAIS retreat (Fig. 4d, g, h) but is found to have little effect beyond 2100 (Extended Data Table 1).

Extended RCP greenhouse gas scenarios are available up to 2500, beyond which we assume two different scenarios: (1) natural decay of CO₂ and no further anthropogenic emissions, or (2) engineered, fast drawdown towards pre-industrial levels with an e-folding time of 100 years. These choices are not intended to be definitive, but serve to illustrate the ice-sheet response to a wide range of possible long-term forcing scenarios.
Future high-resolution ocean-model output is not available on multi-millennial timescales. In our long (5,000-year) future simulations (Extended Data Table 1), CCSM4 ocean temperatures at 400 m depth are assumed to remain at their 2300 values for thousands of years beyond 2300 (until 7000). This assumption is based on the thermal inertia of the deep ocean (thousands of years)\(^2\), its longwave radiative feedback on atmospheric temperatures\(^1\), and its relative isolation from surface variations. The response of the intermediate and deep ocean to atmospheric and surface-ocean warming before 2300 is heavily lagged in time, and consequently deep-ocean warming would continue to lower after CO\(_2\) levels and surface temperatures began to decline after 2500\(^2\). However, at some point several thousand years later, intermediate- and deep-ocean waters would start to cool if CO\(_2\) levels decay as in Extended Data Fig. 7. The trajectory of these temperatures would vary spatially and depend on details of the ocean circulation. To our knowledge, the state of the ocean as it recovers from a greenhouse gas perturbation over these timescales is largely unknown, as relevant coupled atmosphere–ocean global climate model simulations at the resolution and duration appropriate to our ice model have not been run. Consequently, our assumption of constant 400-m ocean temperatures after 2300, although likely to be conservative beyond 2500, may be questionable for the latter parts of the simulations assuming fast, engineered CO\(_2\) drawdown. However, assuming the slow, natural pace of CO\(_2\) recovery\(^7\), its magnitude is based on observed retreat rates of modern large ice cliffs, and additional crevasse depth due to surface melt plus rainfall rate, with a quadratic relationship between proximal ocean conditions and melting at the base of floating ice shelves remains a challenging topic to address. The medium- and long-term future of the ocean, and the changes to the climate system at high resolution are not well constrained by present observations. Yet, studies of future scenarios have shown how a punctuated retreat of the Antarctic ice sheet may trigger a more rapid oceanic and atmospheric response, resulting in a significant sea-level rise. In this study, we explore the consequences of a moderate, near-term stabilization of global atmospheric CO\(_2\) concentrations, which would still lead to increased ocean temperatures and sea-level rise.

Figure 5. Predicted rise in mean temperature over land (left) and ocean (right) from 1850 to 2100 in the RCP2.6 ensemble calibrated against the higher

9

are shown for the three RCP scenarios in Fig. 5, providing both an envelope of sea-level rise (5–15 cm) in an ensemble of future RCP scenarios. An additional ensemble calculation is shown in Extended Data Table 1. The increased variance is caused by three simulations in the RCP2.6 ensemble set, in which the stability of the Thwaites Glacier grounding line is exceeded and the WAIS retreats into the deep interior. Although the ensemble members with bias-corrected ocean temperatures are generally more consistent with observations of recent retreat in the Amundsen–Bellingshausen sector, the validity of the bias correction in the long-term future is unknown.

Extended Data Figure 1 | Warm mid-Pliocene climate and ice-sheet simulation. a, January (warmest monthly mean) difference in 2-m (surface) air temperature simulated by the RCM relative to a preindustrial control simulation with 280 p.p.m.v. CO₂ and present-day orbit. The temperature difference is lapse-rate-corrected to account for the change in ice-sheet geometry and surface elevations. The Pliocene simulation uses 400 p.p.m.v. CO₂, a warm austral summer orbit, and assumes a retreated WAIS to represent maximum Pliocene warm conditions. b, The Pliocene ice-sheet is shown after 5,000 model years, driven by the RCM climate in a, and assuming 2 °C ocean warming relative to a modern ocean climatology. In the model formulation used here, maximum Pliocene ice-sheet retreat with default model parameters is equivalent to 11.26 m GMSL, about 6 m less than in ref. 25.
Extended Data Figure 2 | LIG greenhouse gases, orbital parameters, and RCM climates. a, Greenhouse gas concentrations\textsuperscript{5,72} converted to radiative forcing shows the LIG interval (light red bar) and the best opportunity for ice-sheet retreat. b, Summer insulation at 70° latitude in both hemispheres\textsuperscript{73} (red, south; blue, north) and summer duration at 70° S (black)\textsuperscript{79} shown over the last 150 kyr, and the two orbital time slices (vertical dashed black lines at 128 kyr ago and 116 kyr ago). c, Table showing the greenhouse gas atmospheric mixing ratios (CO\textsubscript{2} in parts per million by volume; CH\textsubscript{4} and N\textsubscript{2}O in parts per billion by volume) and orbital parameters (eccentricity, obliquity, precession) used in the GCM–RCM at the LIG time slices (dashed lines 1 and 2 in a and b), respectively. d–f, January (warmest monthly mean) differences in 2-m surface air temperature relative to a preindustrial control simulation at 128 kyr ago (d), 116 kyr ago (e), and the present-day (2015) (f). Simulated austral summer temperatures at 116 kyr ago (e) with relatively high-intensity summer insolation is warmer than the long-duration summer orbit at 128 kyr ago (d), but unlike the Pliocene (Extended Data Fig. 1a), neither LIG climatology is as warm as the present day, producing little to no rain or surface melt on ice-shelf surfaces.
Extended Data Figure 3 | Effect of Southern Ocean warming on Antarctic surface air temperatures and the ice sheet at 128 kyr ago.
a–c, January (warmest monthly mean) differences in 2-m surface air temperature at 128 kyr ago, relative to a preindustrial control simulation (top row). GHG, greenhouse gas; SST, sea surface temperature. d, e, Ice-sheet thickness (m) after 5,000 model years, driven by the corresponding climate in a–c. a and d, Without climate–ice sheet coupling (present-day ice extent and surface ocean temperatures in the RCM), and prescribed 5°C sub-surface ocean warming felt only by the ice sheet. b and e, With asynchronous coupling between the RCM atmosphere and ice sheet, and prescribed 5°C sub-surface ocean warming felt only by the ice sheet. c and f, With asynchronous coupling between the RCM atmosphere and ice sheet, prescribed 3°C sub-surface ocean warming felt by the ice sheet, and ~2°C surface ocean warming felt by the RCM atmosphere. c shows the locations of East Antarctic ice cores (EDC, EPICA Dome C; V, Vostock; DF, Dome F; EDML, EPICA Dronning Maud Land) indicating warming early in the interglacial and previously attributed to WAIS retreat; this warming is similar to that simulated in c from a combination of ice-sheet retreat and warmer Southern Ocean temperatures, supporting the notion that the timing of LIG retreat was largely driven by far-field ocean influences, rather than local astronomical forcing.
Extended Data Figure 4 | RCM climates used in future, time-continuous RCP scenarios and evolving ice-surface melt rates linked to hydrofracturing model physics. a–d, January surface (2-m) air temperatures simulated by the RCM at the present-day (2015) (a), twice the present level of carbon dioxide, $2 \times \text{CO}_2$ (b), $4 \times \text{CO}_2$ (c), and $8 \times \text{CO}_2$ (d) with the retreating ice sheet. The colour scale is the same in all panels. Yellow to red colours indicate temperatures above freezing with the potential for summer rain, and surface meltwater production.

e–h, Evolving ice-surface meltwater production (in metres per year) in the time-evolving RCP8.5 ice-sheet simulations, driven by a time-continuous RCM climatology (Methods) following the RCP8.5 greenhouse gas time series (Fig. 4a). Black lines show the positions of grounding lines and ice-shelf calving fronts at discrete time intervals—e, 2050; f, 2100; g, 2150; and h, 2500—with superposed meltwater production rates.
Extended Data Figure 5 | NCAR CCSM4 ocean temperatures and oceanic sub-ice-shelf melt rates. a, RCP2.6 ocean warming at 400-m depth, shown as the difference of decadal averages from 1950–1960 to 2290–2300. b, Same as a but for RCP4.5. c, Same as a but for RCP8.5. d, CCSM4 RCP8.5 ocean warming from 1950–1960 to 2010–2020 showing little to no warming in the Amundsen and Bellingshausen seas. The red line shows the area of imposed, additional ocean warming. e, f, Oceanic melt rates at 2015 calculated by the ice-sheet model from interpolated CCSM4 temperatures (e), and with +3 °C adjustment in the Amundsen and Bellingshausen seas (f), corresponding to the area within the red line in d.
Extended Data Figure 6 | Effect of future ocean warming only.

a, Antarctic contribution to future GMSL rise in long, 5,000-yr ice-sheet simulations driven by sub-surface ocean warming simulated by CCSM4, following RCP8.5 (black line), with a +3 °C adjustment in the Amundsen and Bellingshausen seas (blue line; see Extended Data Fig. 5) and a warmer +5 °C adjustment (red line). Atmospheric temperatures and precipitation are maintained at their present values. b–d, Ice-sheet thickness at model-year 5,000, driven by sub-surface ocean forcing from CCSM4 (b) and from CCSM4 with a +3 °C (c) or +5 °C (d) adjustment in the Amundsen and Bellingshausen seas. Note the near-complete loss of ice shelves, but modest grounding-line retreat in b, the retreat of Pine Island Glacier in c, and the near-complete collapse of WAIS once a stability threshold in the Thwaites Glacier grounding line is reached in d.
Extended Data Figure 7 | The long-term future of the ice sheet and GMSL over the next 5,000 years following RCP8.5 and RCP4.5.

**a**, Equivalent CO₂ forcing following RCP8.5 until the year 2500, and then assuming zero emissions after 2500 and allowing a natural relaxation of greenhouse gas levels (red) or assuming a fast, engineered drawdown (blue) with an e-folding timescale of 100 years. **b**, Antarctic contribution to GMSL over the next 5,000 years, following the greenhouse gas scenarios in **a**. The same as **a**, except showing long-term RCP4.5 greenhouse gas forcing. **d**, The same as **b**, except following the RCP4.5 scenarios in **c**. The insets in **b** and **d** show the ice sheet (and remaining sea-level rise) after 5,000 model years in RCP8.5 and RCP4.5, respectively, assuming fast CO₂ drawdown (blue lines), highlighting the multi-millennial commitment to a loss of marine-based Antarctic ice, even in the moderate RCP4.5 scenario. Note the different y-axes in RCP8.5 versus RCP4.5.
Extended Data Figure 8 | Freshwater input to the Southern Ocean.
Total freshwater and iceberg flux from 1950 to 2500, following the future RCP scenarios shown in Fig. 4b. Freshwater input calculations include contributions from ice loss above and below sea level and exceed 1 Sv in RCP8.5.

Antarctic contributions to GMSL for the Pliocene and LIG simulations (rows 1–9) with +2 °C ocean warming in the Pliocene and incrementally imposed ocean warming in the LIG simulations. Values shown represent ice retreat at the end of quasi-equilibrated 5000-yr simulations. Time-continuous LIG simulations forced by proxy-based atmosphere and ocean climatologies (rows 10–12) list maximum GMSL contributions occurring early in the LIG (Fig. 3a). The remaining rows list Antarctic contributions to GMSL at specific times (years as shown) in time-dependent future simulations. Ensemble means and standard deviations (1σ) of the RCP ensemble members listed in Extended Data Table 2 are also shown. Future GMSL contributions are shown relative to 2000.

Varying combinations of three model parameters (first column) correspond to OCFAC, CREVLIQ and VCLIF, respectively (see Methods). The resulting GMSL contributions of each ensemble member driven by Pliocene and LIG climatologies are shown in the second and third columns. Combinations of model parameters satisfying Pliocene and LIG sea-level targets are assigned a Large Ensemble number (LE#) in the fourth column. Default model parameter values (LE# 12) and resulting Pliocene and LIG GMSL rise are in bold type. Four future ensembles using alternative sets of the palaeo-filtered Large Ensemble members and following RCP2.6, RCP4.5 and RCP8.5 emissions scenarios are shown at the right. The top two ensembles use 29 combinations of parameter values that satisfy LIG sea-level targets and a range of Pliocene sea-level targets between 5 m and 15 m. The bottom two ensembles use a more restricted set of 15 parameter combinations that satisfy a higher Pliocene target range > 10 m. Future RCP ensembles at left correspond to the GMSL time series in Fig. 5. The two ensemble sets at far right include the ocean-temperature bias correction described in the text, Fig. 4 and Extended Data Fig. 5. Antarctic GMSL contributions for each ensemble member are shown at 2100 and 2500. Ensemble means and 1σ standard deviations are also shown. GMSL contributions in future ensembles are relative to 2000.

Acknowledgements
The Working Group appreciates the interest and vision of Governor Martin J. O’Malley in establishing the Commission on Climate Change and charging it to develop an objective and science-based assessment of the impacts of climate change on Maryland. It has enjoyed the encouragement and support of the Commission Chair, Secretary of the Environment Shari T. Wilson, and the cooperation of Tad Aburn, Brian Hug, and Elizabeth Entwisle of the Maryland Department of the Environment, and Zoe Johnson, Gwynne Schultz, and Gwen Shaughnessy of the Maryland Department of Natural Resources. Chancellor William E. Kirwan and the presidents of the University System of Maryland encouraged the participation of faculty experts. The preparation of the report was greatly assisted by the generous support of the Town Creek Foundation and the Keith Campbell Foundation for the Environment. Katherine Smith of the University of Maryland Center for Environmental Science (UMCES) assisted in developing the climate change projections from model archives. Jane Thomas and Joanna Woerner of the Integration & Application Network of UMCES assisted with design and report preparation. Special thanks to David L. Evans, Jay Gulledge, Anthony C. Janetos, and Jerry M. Melillo for their helpful reviews of the report.

THE ASSESSMENT

This is an assessment of the likely consequences of the changing global climate for Maryland’s agricultural industry, forestry resources, fisheries resources, freshwater supply, aquatic and terrestrial ecosystems, and human health. It was undertaken by the Scientific and Technical Working Group of the Maryland Commission on Climate Change as part of the Commission’s charge to develop a Plan of Action to address the drivers and causes of climate change and prepare for its likely consequences in Maryland.

The Assessment was based on extensive literature review and model projections. In addition to the scientific literature, other international, national, and regional assessments of the impacts of climate change were consulted. The results from supercomputer models of the responses of climate to increased greenhouse gas concentrations were used to project future conditions for Maryland. These were the same models and scenario assumptions that were used in the acclaimed assessment completed in 2007 by the Intergovernmental Panel on Climate Change (IPCC). Model projections were based on averages for multiple climate models, and selected based on how well they replicated both global conditions and those observed in Maryland during the 20th century. Mean projections for 17 selected models produced more reliable results than individual models. Changes in temperature and precipitation were projected through the 21st century.

In order to estimate the degree of climate change in Maryland that could be avoided by actions to reduce emissions of greenhouse gases, two emissions scenarios were employed. The higher emissions scenario assumes continued growth in global emissions throughout the century, while the lower emissions scenario assumes slower growth, a peak at mid-century, and thereafter, a decline to about 40% of present levels by the end of the century.

RECENT & LIKELY CLIMATE CHANGES IN MARYLAND

Maryland’s climate warmed after the peak of the last Ice Age 20,000 years ago, but has been relatively
stable for the past 6,000 years. Around these long-term average conditions, there have, of course, been variations in temperature and precipitation due to ocean current cycles and solar and volcanic activity. However, atmospheric concentrations of greenhouse gases—gases, such as carbon dioxide, methane, and nitrous oxide, that trap the sun’s energy from radiating back into space—have dramatically increased since pre-industrial times. Carbon dioxide concentrations exceed those experienced over at least the last 650,000 year.

Largely as a result of this increase in greenhouse gases, average global temperature and sea level began to increase rapidly during the 20th century. In its 2007 report, the IPCC concluded that the evidence for the warming of the Earth is “unequivocal.” The IPCC also concluded that most of the observed temperature increase since the middle of the 20th century is very likely due to the observed increase in greenhouse gases.

In evaluating the changes in Maryland’s climate that we are likely to experience over the 21st century, it should be remembered that climatic regimes will continue to vary across the state. Western Maryland has cooler winters and summers and less precipitation during the winter than the rest of the state. Changes that occur will overlay these regional differences, perhaps with some greater warming during the summer to the west than on the Eastern Shore. Temperature is projected to increase substantially, especially under higher emissions. The increase in average summer temperatures in terms of degrees of warming is greater than that in winter. Annual average temperature is projected to increase by about 3°F by mid-century and is likely unavoidable. The amount of warming later in the century is dependent on the degree of mitigation of greenhouse gas emissions, with summer temperatures projected to increase by as much 9°F and heat waves extending throughout most summers if greenhouse gas emissions continue to grow unchecked.

Precipitation is projected to increase during the winter, but become more episodic, with more falling in extreme events. Projections of precipitation are much less certain than for temperature, but the mean projections indicated modest increases of about 10% or so are likely in the winter and spring. Because of more intermittent rainfall and increased evaporation with warmer temperatures, droughts lasting several weeks are more likely to occur during the summer.

**WATER RESOURCES & AQUATIC ENVIRONMENTS**

Increased precipitation in the winter and spring would mean that the water supplies in the greater Baltimore area will probably not be diminished, but the adequacy of summer water supplies in the greater Washington region, which rely on Potomac River flows, is less certain. Any increases in precipitation are unlikely to replace groundwater substantially enough to compensate excessive withdrawals of some aquifers. At the same time, summer droughts may increase groundwater demand for agricultural irrigation.

More intense rainfall resulting from the combined effects of global climate change and localized factors, for example, the influence of the urban canopy on rainfall, is likely to increase peak flooding in urban environments. Continued increase in impervious surfaces attendant with development would exacerbate this problem. Aquatic ecosystems will likely be degraded by more flashy runoff and increased temperatures. Intensified rainfall events and warmer surfaces (roads, roofs, etc.) would result in rapid increases in stream temperatures, limiting habitat suitability for native fishes and other organisms. Higher peak flows and degraded streams would also transmit more nutrients and sediments to the Chesapeake Bay and its tidal tributaries, contributing to water quality impairment in the estuaries.

**FARMS & FORESTS**

Crop production may increase initially, but then decline later in the century if emissions are not reduced. The longer growing season and higher carbon dioxide levels in the atmosphere are likely to increase crop production modestly during the first half of the century. Later in the century, crop production is likely to be reduced due to heat stress and summer drought under the higher emissions scenario. Milk and poultry production would be also reduced by heat stress. These changes will require adaptation by Maryland's agricultural industry, including changes in crop or animal varieties, increased irrigation, and air conditioning for some livestock.

The maple-beech-birch forest of Western Maryland is likely to fade away and pine trees to become more dominant in Maryland's forests. Forest productivity in terms of timber produced is likely to decline late in the century under the higher emissions scenario as a result of heat stress, drought, and climate-related disturbances such as fires and storms. The biodiversity of plants and animals associated with Maryland's forests is likely to decline. Habitat alterations resulting from climate change may force out 34 or more bird species, including the emblematic Baltimore oriole, although southern species may replace them.

**COASTAL VULNERABILITY**

Sea level in Maryland rose by 1 foot in the 20th century, partially because the land is sinking as a result of slow adjustments of the Earth after the last Ice Age. Maryland coastal regions have been subsiding at about a rate of 6 inches per century and should continue at this rate during this century. Additionally, the average level of the sea in this region rose by about the same amount (6 inches) during the past century, resulting in the observed 1 foot of rise of the mean tidal level relative to the land. As a result, Maryland has experienced considerable shoreline erosion and deterioration of coastal wetlands which are a critical component of its bays and estuaries.

Sea-level rise is very likely to accelerate, inundating hundreds of square miles of wetlands and land. Projections that include accelerating the melting of ice would increase the relative sea-level along Maryland's shorelines by more than 1 foot by mid-century and 3 feet by late century if greenhouse gas emissions continue to grow. If sea level rises by 3 feet, most tidal wetlands would be lost—about 200 square miles of land would be inundated. New tidal wetlands developed on newly flooded land would not offset the loss of existing wetlands and significant negative effects on living resources dependent on these wetlands would result. Moreover, if sea level were to rise by 3 or more feet, this would mean that rapid and probably uncontrollable melting of land-based ice was underway and that sea level would rise at an even greater rate during subsequent centuries.

Rains and winds from hurricanes are likely to increase, but changes in their frequency cannot now be predicted. The destructive potential of Atlantic tropical storms and hurricanes has increased since 1970 in association with warming sea surface temperatures. This trend is likely to continue as ocean waters warm. Whether Maryland will be confronted with more frequent or powerful storms depends on storm tracks that cannot yet be predicted. However, there is a greater likelihood that storms striking Maryland would be more powerful than those experienced during the 20th century and would be accompanied by higher storm surges—made worse because of higher mean sea level—and greater rainfall amounts.

**CHESAPEAKE BAY & COASTAL ECOSYSTEMS**

Chesapeake and Coastal Bays restoration goals will likely be more difficult to achieve as the climate in Maryland and the Chesapeake watershed changes. Increased winter-spring runoff would wash more nutrients into the bays, and higher temperatures and stronger density stratification in the estuaries would tend to exacerbate water quality impairment, the alleviation of which is the prime restoration objective. Consequently, nutrient loads would have to be reduced beyond current targets to achieve water quality requirements. Very significant changes are also likely to occur that affect sediment delivery and sedimentation in the estuaries, but are difficult to quantitatively predict. These include potential increases in sediment loads from rivers...
as a result of increased runoff and more erosive extreme discharge events, including those caused by hurricanes, and from shoreline and wetland erosion as a result of accelerated sea-level rise.

Living resources will very likely change in species composition and abundance with warming. A mixture of northern, cool water species and southern, warm water species currently resides in the Chesapeake Bay. Northern species such as soft shell clams and eelgrass are likely to be eliminated later in the century, almost certainly if greenhouse gas emissions are not mitigated. Southern species are very likely to increase in abundance because the milder winters would allow or enhance overwintering populations.

As ocean water becomes more acidic, shellfish production could be affected. Increased atmospheric carbon dioxide concentrations in the atmosphere have already lowered pH in the world's oceans, a trend that is very likely to continue. Recent research indicates that the rate at which oysters and other coastal shellfish build their calcium carbonate shells will likely be affected, but whether this would occur in Maryland waters has not been evaluated.

HUMAN HEALTH

Health risks due to heat stress are very likely to increase, if emissions are not reduced. Under the higher emissions scenario, heat waves are projected to greatly increase risks of illness and death before the end of the century, with an average of 24 days per summer exceeding 100°F. The poor, the elderly, and urban populations are most susceptible. Some, but not all, of these increased risks can be reduced by air conditioning and other adaptation measures.

Respiratory illnesses are likely to increase, unless air pollution is greatly reduced. More ground-level ozone, responsible for multiple respiratory illnesses, is formed under prolonged, high temperatures. Releases of air pollutants (nitrogen oxides and volatile organic compounds) that cause ozone to be formed have been declining, but would have to be reduced much more in a warmer climate to avoid a reversal in progress toward achieving air quality standards.

Increased risks of pathogenic diseases may be less likely. The mortality due to vector-borne and non-vector borne diseases in the United States is low because of public health precautions and treatment, which would likely adapt to changes in disease risks. Climate change might affect the exposure of Marylanders to pathogens such as the West Nile virus, but precautions and treatment could manage this greater risk.

MITIGATION & ADAPTATION

The reduction of greenhouse gas emissions has substantial benefits for Maryland. The mitigation of global emissions by mid-century would very likely result in significantly lower sea-level rise, reduced public health risks, fewer extreme weather events, and less decline in agricultural and forest productivity and loss of biodiversity and species important to the Chesapeake Bay. More serious impacts beyond this century, such as sea-level rise of 10 feet or more, would be avoided.

Based on the projections made in this report, adaptation strategies for human health, water resources, and restoration of Maryland's bays should be evaluated and, where necessary, implemented. Adaptation measures to reduce coastal vulnerability should plan for a 1 foot rise in sea level by mid-century and a rise of at least 2 feet by late in the century. Depending on the course of greenhouse gas emissions, observations, and modeling, planning for increases in sea level of up to 4 feet by the end of the century may be required. The Commission on Climate Change should evaluate additional adaptation strategies related to human health, water resources, forest management, and restoration of the Chesapeake Bay and Maryland's Coastal Bays. The projections of impacts provided in this assessment provide a frame of reference for these evaluations.

Maryland should marshal and enhance its capacity for monitoring and assessment of climate impacts, as a more extensive, sustained, and coordinated system for monitoring the changing climate and its impacts is required. Because of its national laboratories, strong university programs, knowledge-based economy, and proximity to the nation's capital, Maryland is in a strong position to become a national and international leader in regional-to-global climate change analysis and its application to innovative mitigation and adaptation.
Recognizing the scientific consensus about climate change, the contribution of human activities, and the vulnerability of Maryland’s people, property, natural resources and public investments, Governor Martin O’Malley issued an Executive Order on April 20, 2007, that established Maryland’s Commission on Climate Change in order to address the need to reduce greenhouse gas emissions and prepare the State for likely consequences of climate change. The Commission was given the task of developing a Plan of Action to address the drivers and causes of climate change, prepare for the likely consequences and impacts of climate change to Maryland, and establish firm benchmarks and timetable for implementing the Plan.

The Plan of Action includes three components:
1. a Comprehensive Climate Change Impact Assessment,
2. a Comprehensive Greenhouse Gas and Carbon Footprint Reduction Strategy, and
3. a Comprehensive Strategy for Reducing Maryland’s Climate Change Vulnerability.

This report constitutes the climate change impact assessment and thus a key part of the Commission’s Action Plan. It was prepared by a Scientific and Technical Working Group comprised of Maryland-based scientists, engineers and other experts, who worked over ten months to produce this report. Specifically, the Working Group was charged to investigate climate change dynamics, including current and future climate models and forecasts and evaluate the likely consequences of climate change to Maryland’s agricultural industry, forestry resources, fisheries resources, freshwater supply, aquatic and terrestrial ecosystems, and human health. In addition, the Working Group was called
on to advise the Commission and its other working groups as their work proceeded. In particular, the Scientific and Technical Working Group provided information and analysis for the development of the goals for reducing greenhouse gas emissions and for adaptation strategies for reducing coastal vulnerability.

This Comprehensive Assessment of Climate Change Impacts in Maryland is intended to serve a number of purposes. First, it is one of the three legs of the stool for the Commission’s Plan of Action, providing regional context for the importance of reducing Maryland’s greenhouse gas emissions and projections of future climate change for which we should be prepared to adapt. For this reason, projections for climate change and its impacts present two scenarios, one assuming continued growth in greenhouse gas emissions and the other assuming global action to reduce these emissions. The second scenario helps to identify the changes that may be inevitable and for which Maryland must be prepared to adapt. In this manner, it seeks to provide a basis for the development of prudent and effective public policy by the Governor and General Assembly.

Secondly, this Assessment is presented so as to be accessible and comprehensible to the citizens of Maryland as they develop their understanding of this unprecedented challenge to humankind and make personal choices and decisions regarding policy options at local, state, and national levels.

Finally, this Assessment is just the first installment of what must be continuous reassessment of Maryland’s changing climate, the impacts of this change, and what science and engineering can do to understand, predict, and manage these impacts.

Forested mountains and grass meadows of western Maryland.
WHY IS THE WORLD’S CLIMATE CHANGING?

KEY POINTS

› Maryland’s climate has been variable but stable for several thousand years.
  Maryland’s climate warmed after the peak of the last Ice Age and has been relatively stable for the past 6,000 years. Around these long-term average conditions there have, of course, been variations in temperature and precipitation due to ocean current cycles, solar activity, and volcanic activity.

› Atmospheric concentrations of greenhouse gases have dramatically increased.
  Certain gases that trap the sun’s energy from radiating back into space have increased since pre-industrial times. Carbon dioxide concentrations exceed those experienced over at least the last 650,000 years. Average global temperature and sea level began to increase rapidly during the 20th century.

› Global warming is unequivocal.
  The Intergovernmental Panel on Climate Change found the evidence for the warming of the Earth to be “unequivocal.” The IPCC concluded that most of the observed temperature increase since the middle of the 20th century is very likely due to the observed increase in greenhouse gases.

CLIMATE VARIABILITY & CHANGE

Maryland’s climate has changed over millennia as the major planetary forces affecting the Earth’s climate caused glaciers to spread and recede. However, after the peak of the last Ice Age about 20,000 years ago, the climate warmed, most of the glaciers melted, and sea level rose, reaching approximately the present conditions about 6,000 or more years ago. The slow, continued rise in local water levels was mainly the result of the slow sinking of the Earth’s crust beneath us—this itself is a delayed effect of melting glaciers. The first Native Americans came to Maryland as its climate was becoming more moderate and habitable. For most of the time they have been here and all of the time of occupancy by Europeans, Africans and other subsequent migrants, our climate has been relatively stable. Our society, economy, and quality of life has developed under and adapted to this climatic regime.

Of course, our weather (see Section 4 for a discussion of the differences between weather and climate) still varies from year to year—some years are warmer or wetter than others—and even over cycles that extend over several years to a decade or more. This variability is caused by shifts in large-scale processes in the ocean and atmosphere such as the El Niño cycles in the Pacific Ocean, variations in solar activity, and even volcanic eruptions halfway around the world. But, over the past few thousand years, this has caused climate to fluctuate around a rather consistent average.

During the 20th century, however, scientists have concluded that the Earth’s climate was warming and is very likely to warm much more dramatically as a result of human activities that have increased the amount of certain gases in the atmosphere. These gases, most notably carbon dioxide, but also methane and nitrous oxide, trap some of the sun’s energy radiating back out into space, much as the glass panes of a garden greenhouse. The presence of these gases warms the atmosphere sufficiently for life to flourish—without these greenhouse gases the average surface temperature of Earth would be 0°F rather than 57°F. But, as these heat-trapping gases continue to increase the temperature of Earth’s atmosphere and oceans will also continue to increase—this is what is meant by global warming.

MAJOR CHANGES DOCUMENTED

There is no doubt that greenhouse gases in the atmosphere have been increasing. Since pre-industrial times (1750) carbon dioxide concentration has increased by 38 percent, methane by nearly
170 percent, and nitrous oxide by 17 percent. The increase in carbon dioxide has been caused primarily by burning of fossil fuels (coal, oil, and natural gas) and the clearing of forests which held reservoirs of carbon in wood and soils and removed carbon dioxide from the atmosphere through photosynthesis. The increase in the other two major greenhouse gases is mostly due to agricultural activities: methane through growing rice and raising cattle, and nitrous oxide from the application of industrial fertilizers to crops, as well as a result of the high-temperature combustion of fossil fuels.

Carbon dioxide concentration in the atmosphere has increased from a pre-industrial value of about 280 parts per million (ppm) to 384 ppm by 2007 (Figure 2.1), exceeding by far the natural range over at least the last 650,000 years as determined from analyses of air bubbles trapped in glacial ice.

The global mean surface temperature, based on both air and ocean temperatures, has increased by more than 1°F (0.6°C) since 1930 (Figure 2.2), with most of this due to a steady and rapid increase since 1980. Twelve of the last thirteen years rank among the warmest years since 1850, when thermometer measurements became widely recorded. In the Northern Hemisphere, where there are numerous data on temperature proxies such as tree ring thickness and ratios of stable isotopes, neither the recent high global mean temperature nor the rapid rate of temperature increase have been experienced during the last 2000 years.

Global warming affects not only air and ocean temperatures but also precipitation and sea level—ocean waters expand as they warm and as melting glaciers and polar ice sheets further contribute to the ocean's volume. Warmer conditions cause...
more moisture to go into the atmosphere through evaporation and plant transpiration, and this water vapor must come down in the form of precipitation. However, the effect is not uniform, with increased precipitation documented over the middle and high latitudes of the Northern Hemisphere and over tropical land areas, while precipitation declined in the already dry, lower latitude lands.

**WARMING IS UNEQUIVOCAL**

The conclusion that the warming of the climate system is unequivocal and the preceding observations come from the most recent assessment of the Intergovernmental Panel on Climate Change, an international scientific body established by the World Meteorological Organization and by the United Nations Environment Programme. The IPCC was awarded, along with Vice-President Al Gore, the Nobel Peace Prize for its Fourth Assessment Report, released in 2007. The findings of the Panel are careful and deliberate and enjoy the wide acceptance of the climate science community—in fact, scientific criticism that the IPCC was too cautious and reticent is more common than criticism for overstating the case.

The IPCC concluded that most of the observed increase in globally averaged temperatures since the middle of the 20th century is very likely due to the observed increase in greenhouse gas concentrations resulting from human activities. The Panel also found decreases in snow cover and sea ice extent and the retreat of mountain glaciers during this period. Global average sea level rose with increasing ocean water temperatures. Heavy rains increased in frequency in some regions of the world.

Extensive physical and ecological changes resulting from the changing climate are also described in the IPCC assessment, including thawing of permafrost, lengthening of the growing season in middle and high latitudes, shifts in the ranges of animals and plants toward the poles and up mountain elevation gradients, declines in some plant and animal species, and earlier seasonal flowering of trees, emergence of insects, and egg-laying in birds.

The same detailed appraisal of the relationship of the changes in Maryland's climate and the increase in greenhouse gas concentrations has not been undertaken, and indeed is not practical because of the global scale of the climate system. However, the trends of increased temperature, precipitation, and sea level rise and many of the biological changes that have been observed are very consistent with the assessment of the IPCC for North America.

Comparison photos of McCarty Glacier in Kenai Fjords National Park, Alaska. McCarty glacier retreated ~12 miles between the period these two photos were taken and is not visible in the 2004 photo.
The lakes, ponds, and streams of Maryland are a favorite habitat for the twelve-spotted dragonfly.
Approach to Assessing Recent & Future Climate Change

**KEY POINTS**

- The Assessment was based on extensive literature and model projections. In addition to the scientific literature, other international, national, and regional assessments of the impacts of climate change were consulted. The results from supercomputer models of the responses of climate to increased greenhouse gas concentrations were used to project future conditions in Maryland.

- Model projections were based on averages for multiple climate models. Models were selected based on how well they replicated both global conditions and those observed in Maryland during the 20th century. Mean projections for 17 models produced more reliable results than individual models. Changes in temperature and precipitation were projected through the 21st century.

- Higher and lower emissions scenarios were employed. In order to estimate the degree of climate change in Maryland that could be avoided by actions to reduce emissions or greenhouse gases, two emissions scenarios were employed. The higher emissions scenario assumes continued growth in emissions throughout the century, while the lower emissions scenario assumes a slower growth peak at mid-century and declines thereafter to about 40% of present emissions levels by the end of the century.

**THE PROCESS**

The Scientific and Technical Working Group (STWG) developed this assessment using published scientific information on Maryland’s climate and environments, the recent IPCC reports, even more recent scientific literature, and several new assessments of specific issues or region impacts. Particularly important among these assessments were various Synthesis and Assessment Products being produced by the U.S. Climate Change Science Program (some drafts still in preparation or review) and regional assessments, especially the Northeast Climate Impacts Assessment (NECIA). The NECIA, led by the Union of Concerned Scientists, produced two very readable reports on climate change, its impacts and solutions in the northeastern United States, defined as the nine-state region including Pennsylvania and New Jersey northward. Because of its proximity, the findings of the NECIA are highly relevant and have been reflected in the Maryland assessment.

The STWG did not have the time or resources to collect or analyze extensive data or to develop new models of Maryland’s climate, relying instead on the primary or summary literature as described above. It did, however, use the results of the extensive general circulation models that were run on a global scale for the IPCC assessment. Such models are run on supercomputers using common assumptions about future emissions of greenhouse gases and have become increasingly skillful in reproducing the climatic conditions experienced during the 20th century looking backward in hindcast mode. This gives some level of confidence in their ability to project conditions with future increases in greenhouse gases for at least the near future. The models were used by the IPCC in demonstrating that the warming observed over the past 100 years is unlikely to be due to natural causes, such as the sun and volcanoes, alone. Model results that take into account greenhouse gas emissions and the cooling effects of sulfate aerosols, also emitted by burning fossil fuels, are able to reproduce the observed 20th century warming, while those that only account for the natural climate forces do not (Figure 3.1).

While our understanding of the forces that affect the Earth’s climate will improve, the scientific community believes that the current generation of models produces reasonable projections of future climatic conditions. They cannot, of course, predict the weather on a specific place or day, but can represent best estimates of future climatic conditions within a broad region averaged over a decade.
Figure 3.1. Climate models run with just natural forces due to solar activity and volcanoes (blue band) suggest slight declines in global mean temperature during the latter 20th century, while the same models including greenhouse gases and aerosol sulfates from human activities (pink band) show warming very consistent with what was actually observed (solid black line).

OBSERVATIONS

The focus of this assessment is the impacts of future climate change, rather than how much of past climate variability is due to human effects, so the emphasis is on model projections. However, data from stations from the United States Historical Climate Network, corrected for the warming effects of urbanization and the local effects of topography, were used to determine how well models reproduce recent climate in Maryland. These individual weather station records also yield information on the trends in temperature and precipitation that have been experienced.

Beyond temperature and precipitation, sufficiently long records of other climate-sensitive variables are scarce, thus attribution of past changes to climate is difficult. One example of the value of such secondary indicators is the recorded trend toward earlier start of honey production in the Piedmont region.8 Honey production requires both temperatures high enough to maintain larval bees and an ample source of nectar from flowering trees, thus integrating two measures of climate change. Other examples of observed changes in forestry and agriculture, Chesapeake Bay processes, sea level, and hydrology are highlighted later in the report.

PROJECTIONS

In forecasting the storm tracks of active or developing hurricanes, for example, an ensemble of models is used rather than just relying on one. This allows for a ‘best estimate’ prediction within a range of plausible tracks. A similar approach was used in the IPCC Fourth Assessment by employing a group of satisfactorily performing general circulation models all run with the same assumptions for greenhouse gas emissions. The archived files of output from these supercomputer model runs were accessed for this assessment.9 The average of the model outputs yields a better representation of present climate than any single model10 or the small number of models used in the Northeast Assessment.7 This ensemble mean gives the best projections because some model inaccuracies are unrelated to the shortcomings of other models, so they cancel out on average.

This assessment used a similar strategy, beginning with the 24 models used for the IPCC Fourth Assessment model intercomparison. The 17 best performing models were selected based on how well the models reproduce the climate in Maryland over the past century.11 Net error scores were computed for temperature and precipitation based on means, trends over the century, seasonal and ten-year filtered correlations, the standard deviation, and the skill with which the models represent global climate. The subset of better performing models was then averaged over the state of Maryland to estimate changes in future climate in this region.

Because the global models require so many hours of supercomputer time to run, they cannot represent regions as small as Maryland with more than a few grid points (Figure 3.2). Thus, the projected changes over the state need to be considered in the context of the large differences in local state climate. For example, one would expect the climate in high elevation regions of western Maryland to remain cooler than the climate on the coastal plain despite similar temperature increases in both regions (see Table 4.1 in the next chapter). The average seasonal cycle for 1979-1999 is removed from each model output prior to determining future changes. This reduces the effect of individual model biases on the projection of future changes and projects future climate relative to the average conditions around 1990.
EMISSION SCENARIOS

A critical objective of this assessment was to compare future climate impacts under the situation in which greenhouse gas emissions continue to grow throughout the 21st century with the situation that might be realized if global action was taken to reduce greenhouse gas emissions. A similar approach was used in the Northeast Assessment. Two plausible global emissions scenarios were selected from among those used by the IPCC assessments. The higher emissions (A2) scenario assumes a heterogeneous world, with locally self-reliant response to climate change, regional technological and economic development, and faster growing population. The even higher emission, A1Fi, scenario used in the Northeast Assessment was not used because of the limited archived output available for this scenario. The lower emissions (B1) scenario assumes slower population growth, clean technologies are developed and implemented globally, and there is a general emphasis on global solutions to economic and environmental issues.

These scenarios can be viewed representing the ‘business as usual’ response to climate change versus sustained emissions reduction strategy; although the lower emissions scenario was not developed with that specific assumption in mind. However, the scenarios should not be seen as either a floor or ceiling of possible outcomes. Recent growth in carbon dioxide emissions exceed the higher emissions scenario. On the other hand, the emission reduction goals being actively discussed internationally, i.e. reductions of 60-80% by 2050, would, if implemented, reduce emissions more and result in less warming than the lower emissions scenario. Although the IPCC intends to use several specific emissions mitigation scenarios in its next assessment, projections do not yet exist for such scenarios.

While carbon dioxide emissions for the two scenarios begin to diverge significantly around 2025 and decline in the low emissions scenario after 2050 (Figure 3.3), the cumulative emissions begin to diverge only after 2040. Because carbon dioxide is retained in the atmosphere for a long time, the full effects of this divergence are not fully manifest until late in the century. Thus, in the model projections,
there is often little difference between the higher and lower emissions scenarios until after 2050 and the differences increase thereafter.

**CONFIDENCE**

The spread in model predictions is one indication of how well the underlying physics and feedbacks of climate processes are represented. The hydrological cycle, for example, is less well represented than temperature in all of the climate models because coarse spatial resolution of models precludes a good representation of the physics involved in evaporating, transporting, and precipitating water. As a result, we have high confidence in temperature projections for which the physical processes represented in the model are better understood, moderate confidence in trends in temperature extremes, moderate confidence in directional changes in precipitation and other hydrological variables, and relatively low confidence in model projections of precipitation extremes at this scale.

The spread of model projections for a given parameter is used to assess the likelihood of the projected outcome. Throughout this report, the characterization of likelihood of both trends in observations and certainty of projections has followed with the IPCC assessments, except without the discrete probabilities assigned by the IPCC (Figure 3.4). Similar to the assessment of weather and climate extremes by the U.S. Climate Change Science Program13, this approach allows the communication of the level of certainty that is consistent throughout the report.

**ABRUPT CLIMATE CHANGE**

Finally, a word of caution is offered about the use of climate model projections in planning for future climate conditions. There is greater confidence regarding some variables (such as global and regional temperature) than others (such as regional precipitation). Some variables (such as soil moisture or stream flow) result from the complex interplay of temperature, water, carbon dioxide concentrations, and living organisms, making them difficult to model with great reliability. Still others will be influenced by processes that may dramatically change and thus are inherently challenging for scientists to predict (such as the contribution of future polar ice sheet melting to sea-level rise).

Because of the way they are constructed, climate models can be used to assess gradual trends averaged over decades. They are, at this point in their development, less reliable as a signal of more abrupt climate changes. Various records of past climate changes, including deep sea sediments, ice cores, tree rings, and other natural recorders, indicate that they have often taken place within a fairly short period of time, within a century or even a decade. Scientists are actively conducting research on the causes and consequences of such abrupt climate changes, but few attempts have been made to model them under future global warming conditions. For the purpose of this assessment, it is simply important to keep in mind that the changes that will take place during this century may be more ‘jerky’ than continuous, with trends reversing for some years and advancing more dramatically over the period of just a decade. This places a challenge both for our observations of trends and for our ability to adapt quickly.
RECENT & LIKELY CLIMATE CHANGES IN MARYLAND

KEY POINTS

► Climates regimes will continue to vary across Maryland.
   Western Maryland has cooler winters and summers and less precipitation during the winter than the rest of the state. Changes will occur on top of these regional differences, perhaps with some greater warming during the summer to the west than on the Eastern Shore.

► Temperature is projected to increase substantially, especially under higher emissions.
   Average temperature is projected to increase by about 3°F by mid-century and is likely unavoidable. The amount of warming later in the century is dependent on the mitigation of greenhouse gas emissions, with summer temperatures projected to increase by as much as 9°F, and heat waves extending throughout most summers.

► Precipitation is projected to increase during the winter, but become more episodic.
   Projections of precipitation are much less certain than for temperature, but modest increases are more likely in the winter and spring. Because of more intermittent rainfall and increased evaporation with warmer temperatures, droughts lasting several weeks are projected to be more likely during the summer.

THE CONTEXT

The state of Maryland, although comprising only 12,303 square miles, spans diverse geographic and climatic zones, from the flat Coastal Plain, westward to the Piedmont foothills, and the Appalachian Plateau. Well-defined seasons divide the cool, northwesterly wind-dominated dorman season for plant growth from the warm summers with southwesterly winds and high humidity in the coastal regions. Spring and fall are highly variable with weather changing almost daily as warm and cool fronts push through mainly from the west. Although Maryland lies south of the main winter cyclone track, the influence of these storms can affect winter climate. Storms originating in the south or coastal regions (Nor’easters) also play a role in destructive winter weather, as they are accompanied by large amounts of rainfall and high tides. Hurricanes and tropical storms, although infrequent with only eight storms affecting Maryland since 1954, also can have a destructive influence on Maryland Coastal Plain regions in particular, primarily through flooding and storm surge.

Figure 4.1 illustrates the seasonal range of temperature across Maryland. While the higher elevations to the west remain cooler in both winter and summer, the rate of temperature increase from 1977 to 1999, is similar across the state, with an increase in the mean annual temperature of 2°F. No weather stations show a temperature decrease. This is significantly more warming than the global average. The rainfall differences across the state are much smaller, with Maryland having little seasonality in rainfall; consequentially, most agriculture relies on precipitation rather than irrigation (see Section 6). Precipitation is highly variable from year to year, and no clear trend emerges from the stations in Maryland, although significant increases in precipitation have been documented to the north.
Projected temperature increases. On a global scale, temperature increases are generally expected to be greater in the Northern Hemisphere, particularly toward the Arctic regions. Maryland, therefore, will not warm by as many degrees as the New England states. Nonetheless, Maryland will experience significant warming in the coming decades and century (Figure 4.2).

The climate model mean projects an additional 2°F of warming by 2025, regardless of which emissions scenario is followed. By 2050, the policy decisions applying to which emissions path is followed begin to have an effect, and a difference in winter versus summer warming also emerges. The lower emissions scenario warms slightly less by 2050, with summertime temperature increases of nearly 3°F. Temperature under the higher emissions scenario begins to increase sharply after mid-century, with summertime seeing somewhat greater warming than winter.

By the end of the century, the difference between the higher and lower emissions scenario is marked. The low emissions path has held temperature increase to 4.8°F in summer, and 4°F in winter, while the higher emissions scenario leads to warming of nearly 9°F in summer and 7°F in winter in Maryland. One would expect these increases to be above the current mean temperatures for the three regions of the state as shown in Figure 4.1. Summertime average (over both night and day) temperatures in the Coastal Plain would increase from 77°F to 86°F by the end of the century under the higher emissions scenario. However, an ongoing national assessment has produced statistically

**TEMPERATURE**

Human-induced climate change is most directly linked to global temperature rise. However, atmospheric circulation, interactions of climate with land surfaces and oceans, and other factors drive patterns of heating and cooling that affect the
Section 4: Recent & Likely Climate Changes in Maryland

Downscaled maps based on the averages of a similar array of outputs that suggest summertime warming would be greater in Western Maryland and less on the lower Eastern Shore because of the moderating influence of the ocean (Figure 4.3).

These projections have relatively little spread between model projections for a given scenario, thus it is very likely that there will be more warming in summer than winter, and that the higher emissions scenario will result in substantially greater warming than the lower emissions scenario. Confidence in how well models represent the underlying physics of human caused warming is also high. While the likelihood of warming is high, the exact magnitude of the amount of increase is less so. However, none of the models project less than 4°F of warming in summer by 2100.

This is not to say that as the century progresses each year will be warmer than the preceding year. There will likely be months and even years that are on average cooler than the current seasonal norms. This is due to variations in the weather, not changes in climate. This assessment focuses on the average temperature over longer periods, and this continues to increase in all emission scenarios. Thus, any given warm or cold weather episode cannot be unambiguously attributed to climate; rather it is the accumulation of weather over time that gives rise to changes in climate.

Heat Waves

These projections for summer and winter are based on temperatures averaged over a three-month season. However, it is not the average temperature that affects our comfort or health, but rather the daily extremes. A 4°F average warming could be derived from an endless succession of slightly warm days or from average summer days interspersed with intense heat waves (operationally defined here as three or more consecutive days with temperatures exceeding 90°F). Figure 4.4 depicts increases in the number of days with maximum daily temperatures above 90°F and 100°F. In the late 20th century, there was an average of 30 days per year with maximum temperatures in excess of 90°F. Of course, this number would be higher in urban areas, and lower at higher elevation or near the ocean (see Figure 4.1). On the average, temperatures reached 100°F on only about two days per year. Recent trends suggest a moderation in the number of high maximum temperature days in the Mid-Atlantic region, however the monthly average maximum temperature at Maryland weather stations has been increasing faster than the average temperature, suggesting that maximum daily temperature will ultimately follow suit.

The number of days with temperatures exceeding 90°F is projected to double by the end of the century even under the low emissions scenario and triple under the higher emissions scenario in which virtually all summer days would exceed 90°F.
during an average summer (Figure 4.4). Under the higher emissions scenario, the number of days with temperatures in excess of 100°F is projected to increase by a factor of five, with most summer days exceeding this threshold. While at present, heat waves tend to have a limited duration with only a 13% chance per year of a heat wave lasting longer than 20 days, extended heat waves are likely to be much more frequent and longer lasting, especially under the higher emissions scenario (Figure 4.5). In the low emissions scenario, it remains most likely that any heat wave experienced will be of less than 20 days duration; however, the chance of a longer heat wave increases greatly. Under the higher emissions scenario, any given year is more likely to have a heat wave persisting for 140 days or more than it is to not have a heat wave exceeding 20 days. The predictions for increasing heat waves and temperature extremes are likely, with moderate confidence.

**CHESAPEAKE BAY TEMPERATURES**

Climate models currently do not resolve at the scale of estuaries, even for an estuary as large as the Chesapeake Bay (see Figure 3.2). However, observations of Chesapeake water temperatures extend back into the 1940s (Figure 4.6). These observations show a trend of increasing water temperature of 0.4°F per decade, with much of that increase over the past 30 years, consistent with increasing air temperatures. This amounts to a warming of 2.8°F over much of the Bay since 1940.

A statistical model was used to quantify the relationship between air temperature, over the preceding month, and Chesapeake Bay surface water temperature based on these observations. This relationship was then applied to project Bay temperatures as a function of climate-model projections of air temperature. Because the Chesapeake Bay is shallow in most places, surface water temperature is not only closely related to the air temperature, but also reflects temperatures in the shallows where many benthic organisms such as seagrasses, oysters, or blue crabs live. The temperature increases projected by the model average for Chesapeake Bay closely follow the air temperature increase shown in Figure 4.2, suggesting increases of 4°F by 2050 in the higher emissions scenario and 2.5°F for the low emissions path. This additional warming is of a similar magnitude to that observed in the Bay since 1940 (Figure 4.6). By 2100, the model projections suggest warming of 9°F and 5°F for the higher and lower emissions scenarios, respectively.

Another way to express how these temperature changes might affect the ecology of the future Bay, including what plants and animals might live there, is to compare these future conditions with those currently experienced elsewhere along the Atlantic coast where current conditions resemble those projected for the Bay (Figure 4.7). Summertime water temperatures are likely to be similar to those of the North Carolina sounds by 2050. Under the higher emissions scenario, summertime water temperatures in the Bay might approximate conditions in South Florida. The effects of temperature increase and other climate changes on the Chesapeake Bay ecosystem are discussed further in Section 8.
**SECTION 4: RECENT & LIKELY CLIMATE CHANGES IN MARYLAND**

**PRECIPITATION**

There has not been a statistically significant trend in precipitation in Maryland in recent years and this is consistent with the relatively modest changes projected by the climate model ensemble mean (Figure 4.8). Projections of winter rainfall show the greatest change, with increases of 5% by 2025.

![Figure 4.7 - Summertime surface water temperatures in the Chesapeake Bay.](image)

*Figure 4.7. Summertime surface water temperatures in the Chesapeake Bay are projected to approximate those of estuaries well down the Atlantic Coast by 2050 and 2100.*

**BOX 4.1 CHESAPEAKE FREEZE IS LESS FREQUENT**

An ice-covered Chesapeake Bay is an iconic symbol of winter for many Maryland residents. Thin ice presently forms in sheltered embayments in most years. However, at roughly ten-year intervals, the Bay freezes over from shore to shore at the Chesapeake Bay Bridge. While these infrequent ice cover events may have little effect on the ecology of the Chesapeake Bay, they represent an obstacle to shipping, and ice cover reports are routinely issued for Chesapeake Bay by the U.S. Coast Guard. The climate model average predicts that these once every ten-year ice cover events are likely to occur much less frequently in the future: every 25 years for the year 2100 low emissions scenario and as infrequently as once every 40 years under the higher emissions scenario (Box Figure 4.1). Ice cover that occurs every year at present may become less common in the future, with ice in the nearshore environment occurring only every 2-5 years by the end of the century under both the lower and higher emissions scenarios. This may have beneficial implications for nearshore oyster communities (see Section 8).
projected for both scenarios, a 6.6 to 6.8% increase by 2050, and increases of 10.4 to 12.6% by 2090 under the lower and higher emissions scenarios respectively. However, there is a very wide band of uncertainty around these mean tendencies and increases of that scale do not approach the level of present year-to-year variability in winter precipitation. No season is projected to experience a substantial decrease in mean precipitation; however, some models project small declines in summer or fall precipitation and larger increases of up to 40% in winter precipitation by the end of the century. At the same time, large decreases are projected in winter snow volume (25% less in 2025 to 50% less in 2100 regardless of emission scenario). While Maryland does not receive large amounts of snowfall compared with states to the north, these reductions are large enough to reduce the spring river discharge associated with melting snow. Also, snow accumulation is very likely to be less common in western Maryland, thus affecting winter recreational activities.

When precipitation (P) is compared with the loss of water due to evaporation and plant transpiration (ET) that accompany increased temperatures, the water remaining (P-ET) shows little difference between the higher and lower emissions scenarios. However, the mean P-ET difference, reflecting the water available for runoff or groundwater recharge, is projected to decrease by 2 to 7 mm per month during the summer and increase by 6 to 7 mm (or only about one quarter of an inch) per month during the winter by end of the century; spring and fall projections show more modest changes.

Perhaps more relevant than the average rainfall, is how that rainfall is delivered. There is little change projected for the precipitation in the one-quarter of months that are driest. However, the range of precipitation from 25 to 75 percent of the time suggests a trend to increasing precipitation in the wet winter and summer months. The widening
of this range in the projections illustrates that the month-to-month precipitation variability is projected to increase.

One measure of this variability is the amount of rainfall delivered in each rainy day. Climate models typically underestimate this at present, having too many days with weak precipitation. However, even with this shortcoming, the mean of model ensemble projects increases in the amount of rain in any given day. The models also predict an increase in the maximum amount of rainfall occurring in any 5-day period, with the likelihood of getting more than 5 inches of rainfall in a storm event increasing from 5% at present, to 8% for the lower emissions scenario, and to 15% for the higher emissions scenario. These projections, coming as they do from models that are not able to spatially resolve many aspects of the hydrological cycle, are only moderately likely; however, they are broadly consistent with observed trends. More accurate model predictions of precipitation will require development of regional climate models with finer spatial resolution.

The Northeast Climate Impacts Assessment (NECIA) report also projected increases in precipitation over the region to the immediate north of Maryland of up to 10% by the end of the century, with larger increases in winter and little change in summer. Indices of precipitation intensity, number of days with precipitation greater than two inches, and maximum five-day precipitation all showed comparable trends with the higher emission scenario used in that assessment yielding greater effects. The NECIA also found that increased evapotranspiration and frequency of short-term droughts were likely, particularly under higher emissions. This is consistent with this Maryland assessment. The NECIA projected less snow accumulation and earlier snowmelt, higher winter stream flows, and longer summer low-flow periods than at present, and these trends are also reproduced here.

**SOIL MOISTURE**

The effect of changes in temperature and precipitation and their implications for evaporation from water or soil and from plants are integrated in the projections of the changes in soil moisture. In spite of moderate increases in precipitation, increases in temperature in the models lead to decreases in soil moisture throughout the year. This is consistent with recent studies showing a change in the trend in North American soil moisture toward drying over the past 30 years.

Changes represent 10% more drying in summer and fall by 2100 for both emissions scenarios in comparison to present normal summer conditions. Curiously, there is little difference between the lower and higher emissions scenarios, despite the much warmer temperatures projected under the higher emission scenario. This may be due to the very high relative humidity likely to occur, which will limit the rate of evapotranspiration. In years with lower than average rainfall, soil moisture reductions in spring and fall may be important to the local ecosystem and agricultural production. While soil moisture is dependent on the hydrological cycle and thus we have moderate confidence in the underlying physics, there is high agreement among models that summertime soil moisture will decrease, which makes this prediction likely.

**GROWING SEASON**

The length of the growing season is also important to terrestrial ecosystems in Maryland. The climate models project decreases in the number of frost days, where temperatures dip below freezing, and increases in the length of the frost-free growing season (Figure 4.9). Increases in growing season have been observed over the past fifty years. While an increase in growing season may be a boon for gardeners, the increased active growth time coupled

![Figure 4.9](image-url)

Figure 4.9. The number of frost days and growing season length projected before the end of the 21st century under the lower and higher emissions scenarios compared to recent conditions (end of the 20th century). These represent averages for the state and will vary depending on regional differences (Figure 4.1).
with reductions in soil moisture will likely cause some regions of the state to experience increased water demand for crop and landscape irrigation.

Frost days and growing season length are related to model representation of temperature, and so there is moderate confidence in our understanding of the underlying mechanisms driving changes, although the range of the model predictions leads to only moderate likelihood. Nonetheless, all the models predict reductions in frost days and increases in growing season length.

**DROUGHT AND FLOODS**

Global climate models do not capture present day extremes in drought or flood very well. Projections for droughts are probably more reliable than for flood conditions, because droughts reflect the influence of weather patterns that develop over large parts of the United States during periods of weeks to months. Floods, on the other hand, are associated with short-term phenomena and more intense weather events of a smaller spatial and temporal scale than resolved in global climate models. Yet, because these extreme events have such devastating effects on humans, the economy, and the environment, it is critical to estimate how the occurrence of flood events may change in the future to ensure adequate time for developing response strategies.

The models project an increase in the duration of annual dry spells, from about 15 days on average at present, to 17 days for the higher emissions scenario, and a smaller increase under the lower emissions scenario. Most of this increase is projected to occur during the latter part of the century. Based on these projections, it is likely that summer-fall droughts of modest duration will increase, especially after the middle of the century and that under the higher emissions scenario, there will be longer periods without rain. This has greater significance for soil moisture and attendant agricultural drought than for water supply. However, it is not the average that affects agricultural drought, but rather the more extreme or unusual events. The models suggest that, at present, a month-long drought can be expected to occur every 40 years, but this might increase to occurring every 8 years in 2100 under the higher emissions scenario, and there would be no appreciable change for the lower emissions path.

Even for drought conditions, it is important to point out that model projections of the two emission scenarios are based on averaging the output of different models, each of which was run for a continuous period extending from 1980 through 2100. Because each model simulation is the result of a single model run rather than multiple runs from which probabilities can be assigned, the modeling results cannot accurately predict rare events with low probability of occurrence (e.g., such as a 100-year or longer recurrence interval). Thus the projections reported here provide guidance on the likelihood of moderate drought conditions, but cannot represent the probability of an extreme multi-year drought such as the drought of the mid-1960s. Water-supply drought is more heavily affected by periods of low precipitation extending over multiple months, and is most strongly correlated with dry periods persisting through winter and spring when soil moisture, water tables, and reservoir levels would normally experience recharge.

Long-term or water-supply droughts, where rainfall deficits of more than 14 inches persist over a period of two years or more occur slightly less than 4% of the time at present in both observations and the models (Figure 4.10). While this number increases slightly to 5% under the higher emissions scenario, the models do not predict a likely increase in incidence of long-term drought. In contrast, the models suggest that two-year precipitation excesses of more than 14 inches, which are almost never observed but occur 4% of the time in the models, will occur much more frequently in the future. The higher and lower emissions scenarios have 14 inch excesses in precipitation occurring 28% and 14% of the time respectively. Thus, the models predict that while some moderate increase in short-term droughts may occur, increases in extreme precipitation events are more likely in the long-
Heavy downpours have become more frequent and intense in the U.S.

Changes in precipitation extremes in the United States are already apparent in weather records. A report to be published later this year for the U.S. Climate Change Science Program (CCSP) concludes that extreme precipitation episodes (heavy downpours) have become more frequent and more intense in recent decades over most of North America and now account for a larger percentage of total precipitation. Intense precipitation (the heaviest 1% of daily totals) in the continental U.S. increased by 20% over the past century while total precipitation increased by 7%. The CCSP report further concludes that the increase was consistent with increases in atmospheric water vapor, which have been associated with warming resulting from the increase in greenhouse gases, and that precipitation is likely to become less frequent and more intense. Under a medium emissions scenario, daily precipitation so heavy that it now occurs only once every 20 years is projected to occur approximately every eight years by the end of this century over much of eastern North America.

For Maryland, the observed increase in frequency of extreme precipitation has to this point only been 3%, which is not a statistically significant increase. However, significant increases in intense precipitation of as much as 41% have been documented for West Virginia, Delaware, and Pennsylvania. As was mentioned in Section 2, as the world warms increases in precipitation are expected to be greater at higher latitudes than lower latitudes. Maryland sits at the transition between the northeastern region where increases in precipitation are very likely in winter and spring, and the southeast region where projections of changes in precipitation cannot be confidently made.

At present, a watershed in Maryland might experience more than 8 inches of rain in a single day only once every 100 years. The climate models, however, consider 2.5 inches of rain in a single day to be a 100-year event. This is partly because the 2.5 inches of rain is spread evenly over more than 15,000 square miles in the model and because it does not provide high resolution at smaller scales (see Figure 3.2).

The percent of total rainfall coming in extreme events is projected to increase modestly but steadily during the century, with a slightly larger increase under the higher emissions scenario. However, this does not necessarily mean that less rain will fall the rest of the time. The model averages project only small changes in the number of days with more than 10 mm (about four tenths of an inch) of precipitation, with a slight increase under the lower emissions scenario and a slight decrease under the higher emissions scenario, by the end of the century. Five-day maximum precipitation is projected to increase more consistently from approximately 88 mm presently to 95-97 mm (i.e., from 3.4 to 3.8 inches), with little difference between higher and lower emissions scenarios. The maximum one-day precipitation over a year, a decade, and a century is projected to increase more, particularly under
the higher emissions scenario near the end of the century (Figure 4.11). The projected increases are greater for longer recurrence intervals, consistent with increasing climate volatility. But, again, it's important to remember that the global climate models have limited ability to project extreme rainfall events and tend to underestimate extreme precipitation events.

![Figure 4.11. Projected one-day maximum precipitation for 1, 10 and 100 year return frequencies. Models tend to under-estimate extreme precipitation amounts, so the relative comparisons rather than the actual amounts are relevant.](image-url)
SECTION 5: WATER RESOURCES & AQUATIC ECOSYSTEMS

KEY POINTS

> Increased precipitation would supply reservoirs but not alleviate overdraft of aquifers.

Water supplies in the greater Baltimore area should not be diminished, but the adequacy of summer water supplies in the greater Washington region is less certain. Any increases in precipitation are unlikely to alleviate the present over-withdrawal of groundwater and summer droughts may increase groundwater demand for irrigation.

> Urban flooding will likely worsen because of intensification of rainfall events.

More intense rainfall resulting from large-scale and localized (e.g., urban canopy) climate effects are likely to increase peak flooding in urban environments. Continued increase in impervious surfaces attendant with development would exacerbate this problem.

> Aquatic ecosystems will likely be degraded by increased temperatures and flashy runoff.

Intensified rainfall events and warmer surfaces (roads, roofs, etc.) would result in rapid increases in stream temperatures, limiting habitat suitability for native fishes and other organisms. Degraded streams would transmit more nutrients and sediments to the Chesapeake Bay and its tidal tributaries.

The natural waters of Maryland provide essential habitat for aquatic life and support the fundamental needs of every economic sector of society. The water cycle and the physical and chemical character of natural waters are both strongly dependent on climate patterns and trends, including average and extreme weather conditions, such as floods and droughts, that although infrequent are very important. Although this assessment is intended primarily to address predictions associated with climate change, it is important to recognize that such changes will occur in the context of continuing population growth and economic development. Past experience strongly suggests that the combined impacts of climate change and development on water resources and aquatic ecosystems will be far greater than those of climate change alone. Therefore, reasonable predictions about Maryland’s future must consider both factors.

This assessment addresses: (1) reliability of freshwater supply, including both surface water and groundwater; (2) changes in flood hazards; (3) effects of changes in runoff and water temperature on aquatic habitats and populations; (4) impacts on water quality with implications for management and regulation of sediments and nutrients; and (5) potential salt contamination of aquifers and freshwater intakes as the boundary between fresh and brackish water shifts with rising sea level. These impacts are examined with reference to climate projections based on the higher and lower emissions scenarios (see Section 3). The projections (Table 5.1) are broadly consistent with previous assessments conducted for the Mid-Atlantic region and to a large extent with the Northeast Climate Impacts Assessment.

**FRESHWATER SUPPLY**

Water stress—the imbalance between water demand and available supply—is anticipated to increase in many areas of the world over the coming decades. This is partly a result of increases in demand and partly a result of decreasing availability in some areas. Water availability must be examined not only in terms of average conditions, but also with respect to the amounts available during droughts that are expected to recur periodically. From a global perspective, the region including Maryland is considered as relatively low stress with regard to the projected ratio of water withdrawals to availability under the higher emissions (A2) scenario for 2050.21

As the Advisory Committee on the Management and Protection of the State’s Water Resources noted in 2004: “Nature provides Marylanders with abundant water, which, if well managed, could meet present and future needs.”

On the other hand, this same report identifies potential threats to water quantity and water quality resulting from population growth and land development. And, as recent difficulties in the southeastern U.S. demonstrate, the eastern seaboard is certainly not immune to drought.22 Within the last six years in Maryland, we have witnessed two of the driest years on record as well as the wettest year on record, and there have been impacts on water supplies during the dry years that required public response. These short-term variations are larger than the range of variation in mean precipitation or moisture availability during this century predicted using global climate models. Sensitivity of water supply to wet and dry cycles is in large measure a function of the nature of the water-supply system, together with the array of management options that are available to be used during times of shortage.

Recent evidence suggests that summer drought may be correlated with patterns of sea-surface temperature—a consequence of multi-year cycles in the Atlantic (Atlantic Multidecadal Oscillation) or Pacific (El Niño-Southern Oscillation and the Pacific Decadal Oscillation) oceans—and that these correlations might be used in drought forecasting over time periods of one or two decades.24 It has been suggested that superimposing these cycles on longer term trends projected by global climate models could improve forecasting of drought probabilities and provide a tool for water-supply management for the greater Washington area in adaptation for global warming.25

The Advisory Committee pointed out that total water use in Maryland has not increased even with the increase in population (Figure 5.1).26 This reflects a complex set of changes in water used by different economic sectors, with declining industrial and commercial use and increasing domestic use, public supply, and irrigation. Demand is anticipated to rise over the next 30 years, coinciding with increased suburban land development, affecting

Figure 5.1: Trends in Maryland’s water consumption and population.24
areas that might otherwise be available for recharge of groundwater, and with increased irrigation needs on agricultural land during summer droughts anticipated with the warmer climate. Summer water demand will increase as temperatures increase and water availability during the summer becomes less reliable. Options for demand reduction do exist but have not been fully explored by utilities and public agencies.

Marylanders rely both on surface water, derived from free-flowing streams and from storage in water-supply reservoirs, and on groundwater retrieved from wells in both shallow and deeper confined aquifers. The relative importance of these sources varies both as a function of urban versus rural location and physiographic province (Figure 5.2). Surface water is the primary source in and around major metropolitan areas with about 3.2 million of the state's population of 5.4 million (based on 2004 estimates; present population is at least 5.7 million) served by public water supply in the Baltimore and Washington, D.C. metropolitan areas. Public and community water-supply systems elsewhere, using a mix of surface water and groundwater, served a cumulative population of 1.3 million. Groundwater is the primary source of supply in rural areas where public water is not available and in most of the Coastal Plain, with 900,000 people relying on private wells. Surface water withdrawals increased by 6% between 1985 and 2000, whereas groundwater withdrawals increased by 21%.

Groundwater withdrawals increased by 21% between 1985 and 2000

Although agriculture accounts for only 3 to 5% of state water use at the present time, agricultural needs of 285 million gallons per day (mgd) statewide are anticipated by 2030—more than currently used by the Baltimore metropolitan area. Much of this increased demand will be associated with irrigated agriculture on the Eastern Shore. Furthermore, over half of the new households anticipated by 2030 will likely be located in the rapidly growing counties of Howard, Harford, Frederick, Carroll, Charles, Calvert, and St. Mary's. Many of these counties are already experiencing water stress because of rapid exploitation of local supplies, resulting in building moratoria in parts of Carroll County and rapid declines in well levels in confined aquifers of southern Maryland.

Surface water

The major metropolitan water-supply systems in Maryland rely on a mix of impoundments and direct withdrawal from major rivers. Baltimore City supplies water to Baltimore County as well as a portion of the public water-supply needs of Anne Arundel, Howard, Harford, and Carroll counties. The City has three major water-supply reservoirs with cumulative storage of 86.7 billion gallons, as well as a pipeline that can be used to augment the reservoir supply with water from the Susquehanna River during times of extreme drought. Cumulative safe yield of the reservoirs is nearly 240 mgd and the intake on the Susquehanna River currently has a capacity of 250 mgd with ultimate capacity of 500 mgd. There are additional pumping stations on Deer Creek that can expand capacity further if necessary.

The climate change scenarios described in Section 3 suggest an increased frequency of short-term drought despite a net increase in average annual flow. Baltimore has managed to weather two severe droughts since 2000 without serious negative impacts, although it was necessary to pump water from the Susquehanna and this involved increased treatment costs. It is likely that Baltimore City’s water-supply system should be sufficient to meet demands under the projected climate change. Greater winter-spring precipitation will increase the likelihood that reservoirs will be full heading into the drier summer periods, resulting in protection from water-supply shortages for areas served by the reservoirs.

The Washington Metropolitan Area’s water supply situation is somewhat more precarious. Average annual water use (including Maryland, D.C., and Virginia users) currently is about 488 mgd and projections call for an increase to 572 mgd by 2025. About 75% of the water supply is derived from the Potomac River, the flow of which is largely

Figure 5.2. Maryland’s five physiographic regions.
unregulated. A total storage volume of about 17 billion gallons is available in reservoirs to augment the supply of the Potomac River during dry periods, and additional storage of about 18 billion gallons is available in other suburban reservoirs that do not connect directly to the Potomac supply. A Water Supply Coordination Agreement and a Low Flow Allocation Agreement among the various water suppliers are intended to coordinate the operation of all the water utilities in the region and to allocate shortfalls when water is insufficient to meet all demands.

The Interstate Commission on the Potomac River Basin (ICPRB) has estimated that the existing system is adequate to meet 2025 demand, and even 2045 demand, under a repeat of the worst historical drought conditions. The ICPRB concluded that, even accounting for uncertainties associated with climate change, contingencies in place to restrict demand could be used to avert a water-supply crisis. However, Maryland’s Advisory Committee on the Management and Protection of the State’s Water Resources observed that planning has been complicated by the outcome of a 2003 Supreme Court case that gave Virginia the right to remove water from the Potomac River without following Maryland’s permit regulations. Furthermore, even if this issue can be resolved by mutual agreement, other measures, including development of additional supplies and water reuse, may be necessary to meet local needs.

Groundwater
Groundwater in the Piedmont and Appalachian Plateau regions occurs principally in fractured bedrock and the overlying layer of weathered material that can be as much as 100 feet thick (Figure 5.3). The volume of storage available in these shallow aquifers is typically quite limited and there are strong connections between groundwater and local surface water, such that a reduction in groundwater storage is likely to be reflected in reduced base flow to local streams. Because of the complex flowpaths and connectivity of the fracture network, the spatial pattern of groundwater availability is unpredictable and is therefore unsuitable for large-scale water-supply development. Groundwater availability is sensitive to short-term climate fluctuations and to alteration of the land surface by development. These factors, plus the growing demand, led to the building moratoria near Westminster in Carroll County that were mentioned previously.

Although climate models generally project changes in water availability under average conditions, the likelihood of more frequent short-term drought poses a challenge to the reliability of water supply dependent on shallow groundwater during the late summer and fall in rural areas. Even with significant increases in winter and spring precipitation, it is not clear how much of the increase will contribute to recharge of groundwater in the Piedmont and Appalachian provinces if significant amounts are instead diverted to increased runoff.

The situation in the Coastal Plain of Maryland is quite different. Most groundwater is stored in deep, confined aquifers (Figure 5.4) that are not in direct contact with the surface or with overlying streams. Because the water that recharges these

![Figure 5.3. In the Piedmont, shallow wells draw from unconfined weathered bedrock and deep wells from bedrock aquifers.](image)

![Figure 5.4. Schematic cross-section of the Coastal Plain aquifer system.](image)
aquifers may travel over long distances, these aquifers are not sensitive to short-term weather fluctuations. They are more likely to experience changes in storage and in well levels that are tied to long-term trends in the balance between recharge and water withdrawal. Thus, climate change projections in which precipitation increases more than evapotranspiration are less likely to pose a serious problem for aquifer storage, even if there are short-term droughts superimposed on the long-term trends.

A serious challenge does arise, however, as a result of pumping trends associated with rapid urban and suburban development in the Coastal Plain counties. Long-term trends showing declining well levels have accelerated sharply since the 1980s (Figure 5.5). In many cases, the rate of decline exceeds 2 ft/yr and in the areas of most active pumping it can be substantially higher. The Maryland Department of Environment uses an 80% rule to regulate groundwater extraction from confined aquifers—pumping is not supposed to lower well levels more than 80% of the distance between the pre-pumping water level and the top of the confined aquifer. At present, however, farmers are not required to report the amount of water pumped for irrigation and there are significant ongoing monitoring studies to document head losses associated with irrigation. While the declines in well levels currently observed are mainly a result of urban and suburban uses, this lack of reporting and monitoring could pose a problem if demand for crop irrigation substantially increased.

If the regional declines in confined aquifers continues or accelerates, regional land subsidence over the affected areas may exacerbate local relative sea-level rise as discussed in Section 7. Changes in freshwater storage and in relative sea level may also cause the freshwater/saltwater boundary illustrated in Figure 5.4 to move landward and to reach shallower depths. This may pose a particular problem for withdrawals from shallow aquifers on the Eastern Shore.

**FLOOD HAZARDS**

Because floods represent the extreme end of the frequency distribution of streamflows, prediction of flood probabilities is subject to uncertainty even under the best of circumstances. Estimation of the probability or return period of a flood of a given size typically is accomplished using historical records, and standard estimation techniques assume that flood occurrence is essentially a random process and that the underlying probabilities are not changing over time. Therefore, climate change presents a challenge to standard approaches in flood-frequency estimation because the future will no longer resemble the past.

Trends toward increased river runoff are already apparent beginning about 1970 in portions of the eastern United States, including the Mid-Atlantic region. Annual runoff has further been projected to increase in the eastern United States by the middle of this century, consistent with increases in atmospheric water vapor and precipitation intensity. The probability of occurrence of a great flood (defined as having a 100-yr return period) in a number of large river basins had increased substantially during the 20th century, prompting a group of leading hydrologists to write recently that climate change has undermined a basic assumption about the relevance of past observations for management of future water supplies, demands, and risks. The authors suggest that new modeling approaches are needed to improve our ability to estimate flood hazards under alternative future scenarios. Although intense rainfall is the most important contributor to flood hazards, there are other aspects of land-surface conditions that determine how efficiently intense rainfall is converted into flood flow. These cannot be predicted on a statewide basis for all watersheds with information that is currently available; therefore, this report focuses on the probability of intense precipitation as the primary indicator of flood probability.
The Susquehanna River Basin is one of the most flood-prone watersheds in the nation. The main stem and its tributaries drain 27,510 square miles of New York, Pennsylvania, and Maryland.

As discussed earlier, probabilities of flood inducing rainfall are not well represented in global climate models that predict average conditions over large grid cells. A possible exception would be large-scale events such as powerful extratropical storms occurring in winter, particularly where rain on snow is a key element. These may generate large floods over very large drainage areas comparable to the model grid cells. Such events occur infrequently in Maryland, but can be important in the Susquehanna River Basin, which lies mostly in Pennsylvania and New York and supplies about one-half of the freshwater inflow to the Chesapeake Bay. The January 1996 flood in the Susquehanna River basin is an example of such an event. The magnitude of the flood was in part a result of the large volume of moisture already stored on the landscape in the form of snow, which was released very rapidly as it melted during the precipitation event. Although climate models project higher precipitation totals and greater intensity of rainfall during the winter season, the reduction in volume of snow stored on the landscape may well cause a reduction in the likelihood of this type of extreme flood even as moderate floods become more likely in winter and early spring.

Another major cause of flood hazards in the region is the occurrence of hurricanes and tropical cyclones. The flood of record for many locations in Maryland (including the Susquehanna River at Conowingo Dam) is still Hurricane Agnes, which struck the region in June 1972. By the time it reached Maryland, Agnes was not a major cause of storm surge, wind damage or coastal flooding; its primary impact was as a rainfall-runoff event. Hurricane Floyd, in September 1999, dropped as much as 12.6 inches of rain on Maryland’s Eastern Shore and generated floods in some Eastern Shore rivers with estimated return periods of 100-500 years. As discussed in greater depth in Section 7, the current scientific consensus is that tropical cyclones are projected to increase in rainfall intensity even though their frequency may decline.

For small watersheds, the likelihood of flooding depends not only on total amount of precipitation but also on its intensity at smaller spatial and temporal scales. While climate models may be useful for projecting maximum one-day precipitation averaged over a large area (Figure 5.2), they cannot predict the actual rainfall over short periods or areas at a scale comparable to a storm cell. Point and small-area rainfall intensities associated with flood generation will be much higher. This is illustrated by comparing the predicted probabilities of intense precipitation from the model projections with precipitation frequencies based on regional observations for points within the Baltimore-Washington metropolitan area (Table 5.2). Observed rainfall amounts associated with recurrence intervals of 1 to 100 years are already 170 to 300 percent greater than the one-day rainfall amounts projected from the climate models near the end of this century. If flood magnitudes change in a manner commensurate with the trends in maximum rainfall predictions (Figure 4.11), then one might indeed
expect to see larger, more extreme floods in smaller watersheds as the century proceeds. The magnitude of such an increase is necessarily speculative; the point values of extreme rainfall under the present climate are already so much higher than those predicted by these GCM scenarios that only the general trends are relevant, and they are not based on simulation of the actual physical processes associated with extreme precipitation. Nevertheless, if one accepts the comparisons in maximum one-day rainfall as representative of likely changes in flood magnitude, then we might anticipate a 20% increase in the magnitude of the 100-year flood under the higher emissions scenario and a 10% increase under the lower emissions scenario. Comparable increases for the 10-year recurrence interval would be approximately 29% and 16%, respectively, with the increase in peak flood flows under higher emissions approximately double the increase under lower emissions.

These increases are consistent with the trends identified by the IPCC Fourth Assessment, the Northeast Climate Impacts Assessment, and the U.S. Climate Change Science Program concerning the increased likelihood of intense, flood-generating precipitation. However, it is important to remember that land development has had and will continue to have a major effect on increasing flood probabilities in smaller drainage areas. As the area of impervious surface and storm drain networks increase, runoff is accelerated. Also, as was demonstrated with a 2004 event in Baltimore, the urban ’canopy’ effect can play an important role in determining the conditions favoring intense thunderstorms.

Because of both these effects—surface properties affecting runoff response and atmospheric interactions affecting rainfall intensity—flood peak magnitudes in small urban watersheds may be several times larger than for comparable rural watersheds. This can be illustrated by plotting flood peak discharge as a function of drainage area for thunderstorms in Baltimore compared to some record floods in the Mid-Atlantic region (Figure 5.6). The straight lines are thresholds defining the upper range of extreme flood peaks that may attain values between 1000 and 2000 cfs/ mi². The urban floods were, with one exception, events with recurrence intervals of the order of 5 to 10 years; yet these events, represented by blue dots on the plot, were comparable in magnitude to Mid-Atlantic floods that occur much less frequently.

The increased frequency and magnitude of floods in urban watersheds has implications not only for flood protection and water allocation, but also for the design of treatment plants, dams, and even bridges. Prediction of future estimates will require the development of new modeling approaches that can incorporate the effects of changing climate superimposed on trends in urban development. Using such an approach, a recent study projected that the number of days with extreme rainfall in the New York metropolitan area is likely to increase from 1-2 days to 3-4 days by the end of the summer under the higher emissions (A2) scenario. Building on efforts like this one, smaller scale atmospheric models linked with global climate models could more accurately project precipitation and those predictions could be used to drive hydrologic models to predict flood probabilities associated with combined climate change and urbanization scenarios.

**WATER QUALITY & AQUATIC BIOTA**

Freshwater ecosystems provide multiple goods and services (Table 5.3) valued highly by people and inextricably linked to water flows and the interaction of flow with the landscape. The ability of aquatic ecosystems to provide these benefits depends on how ’healthy’ they are—that is, the degree to which physical and biological processes that maintain normal ecological functioning are working properly. Climate changes may modify these critical processes and thus diminish the health of the ecosystem.

Of particular concern are climate-induced changes that exacerbate human-caused stresses,
Table 5.3. Freshwater ecosystems (wetlands, rivers, streams, lakes, etc.) provide a number of goods and services that are critical to their health and provide benefits to society. The major services are outlined along with the ecological processes that support the function, how it is measured, and why it is important.45

</table>

A beautiful day is enjoyed on a family hike in western Maryland.
such as depletion of water flows and urbanization, both of which are already affecting streams and rivers over much of the State. As is the case with flood probabilities, the influence of urban development signal is likely to be at least as strong through the remainder of this century as the climate signal, and these two signals combined will tend to reinforce trends pointing in the same direction, i.e., more highly variable flows. Global warming will also directly change the temperature regimes, causing shifts in the species inhabiting the ecosystems.

Anticipating the future condition of a river in the face of climate change requires explicit consideration not only of the current climatic, hydrologic, and ecological conditions but also of how it is currently managed and how human behavior will affect the ecosystems. Thus, consideration of how climate change is likely to impact Maryland's freshwater ecosystems rests not only on the assumptions underlying climate models and scenarios, but also on future decisions regarding water use and watershed management. Options also exist for adapting these practices to reduce the impacts of climate change on freshwater ecosystems.

Except for deep reservoirs, fresh waters are generally well mixed and respond to changes in atmospheric conditions fairly readily. Thus, they would become warmer as air temperatures increase. As the water warms, individual growth and reproductive rates of biota are expected to increase so long as thermal tolerances are not exceeded. Faster growth rates and time to maturation typically result in smaller adult size, and, because size is closely related to reproductive output in many aquatic organisms, population sizes may decline over time. The spawning time of native fish may also shift earlier if waters begin to warm earlier in the spring, and species that require prolonged periods of low temperatures may not survive.

For fish, amphibians, and water-dispersed plants, habitat fragmentation due to small dams (which are surprisingly common in Maryland's streams) or the isolation of wetlands and tributaries due to drought conditions may also result in elimination of their local populations. Because higher temperatures result in lower concentrations of dissolved oxygen in all but swift flowing waters, this may present an additional stress on organisms.

Aquatic ecosystems in watersheds with significant urban development are expected to experience not only the greatest changes in temperature, but also greater temperature spikes during and immediately following rain storms that could result in the local loss of species. Such temperature spikes of 6 to 12°F occur in urban streams near Washington, D.C., and are strongly related to the amount of warm impervious surfaces (Figure 5.7). A recent modeling study demonstrated how the combined effects of urbanization and climate change on suburban Washington streams would be greater than either alone. Under a moderate emissions (B2) scenario, warming produced an increase in stream temperatures of 6°F late in the century, while urbanization produced an increase of 7°F (Figure 5.8). However, when both urbanization and climate change were imposed, an increase of over 12°F resulted. The urbanization effects alone would stress 8 of the 39 fish species, but with additional effects of climate change, as many as 29 species would be stressed. Almost every recreationally important species (trout, bass, yellow perch, and bluegill) would experience decline in the growth and reproduction ranging from 40% to 90%.

Changes in flow regime toward greater frequency

![Figure 5.7](image-url) Temperature record for an urban stream north of Washington, D.C. Grey spikes represent episodes of warm runoff immediately following rain. Spikes such as these are largely dampened in watersheds with low levels of impervious cover.
of both wetter and drier conditions are projected under both the higher and lower emissions scenarios. While these changes are anticipated to be incremental, similar but much stronger effects are observed in urbanizing environments. Storm runoff occurs more rapidly and generates higher velocities and larger flood peaks, with serious consequences for the aquatic biota. Higher peak flows associated with urbanization result in well-documented decreases in native biodiversity. Higher flows increase suspended sediment and bedload transport, which interferes with animal feeding, while subsequent sediment deposition reduces the habitat availability for insects and spawning areas for fish. Where flows increase sufficiently to prevent sediment deposition, eroded sediment will ultimately be deposited downstream or in the estuaries fed by the rivers and streams. The higher flows and increased inputs of sediment typically degrade stream habitat quality even when there is no net sediment deposition.

Increased flashiness and higher runoff peaks are likely to mobilize chemicals associated with sediment particles. Changes in the transport and processing of nutrients and organic matter are likely, but difficult to predict under changing climatic conditions. There is a considerable uncertainty about how rates of ecological processes affecting nutrients in wetlands and streams—an important factor in affecting the amount of nutrients reaching the already over-enriched Chesapeake Bay—will be influenced by climate change. Dissolved inorganic nitrogen (as nitrate) levels may decrease if rates of denitrification are increased by higher temperatures and associated lower dissolved oxygen levels. On the other hand, if discharge and sediment transport increase, then the downstream movement of nitrogen (as ammonium or organic nitrogen) and phosphorus (as phosphate) may increase. Concentrations of toxic contaminants in the form of petroleum hydrocarbons and combustion byproducts, metals, pesticides, and other organic compounds are typically much greater in urban settings and are related in part to the density of roads and efficiency of storm sewers in conveying materials from impervious surfaces directly into the drainage network. Additional sources of trace contaminants may be derived from leaking sanitary sewers and include oxygen-demanding organic matter, pathogens, and a whole class of emerging contaminants including pharmaceutical compounds and trace constituents from personal care products.

Drier conditions during summer months are likely to result in the loss of small wetlands and intermittent or ephemeral streams, potentially resulting in negative impacts on the water quality downstream. This impact will be particularly exacerbated in urbanized regions. With increased impervious area and less infiltration, there is less groundwater storage and lower baseflows in urban streams than in more natural streams. However, baseflow during dry periods could also be augmented by some combination of leaking infrastructure and lawn irrigation. A tendency toward reduced infiltration and baseflow would tend to exacerbate the lower summer stream flows projected by the climate models, while any baseflow augmentation would reduce the impacts of summer dry periods. Wetlands and streams experiencing reductions in water levels or baseflow often have stressed biota and stream-side vegetation, reduced dissolved oxygen levels, and loss of habitat for species that depend on currents. Physiological stress and increased predation resulting from crowding, combined with habitat fragmentation (isolated stream pools and wetlands), may dramatically reduce survival and constrain dispersal.
Herbicides are applied to a farm field.

Crop production is likely to be reduced under the higher emissions scenario.
Maryland's landscapes, from the high mountains of the Appalachian Plateau to the barrier islands of the Eastern Shore, provide diversity and enjoyment to its people and visitors as well economic wealth from the productivity of its farms and forests. This section addresses the potential impacts of climate change on the land, including the living resources that are exploited economically and other natural resources that provide indirect services to us, not the least of which provide recreation and aesthetic satisfaction.

Prediction of the future of Maryland's natural resources is subject not only in the projections of climate model, but also because of the complexity of the responses of both living organisms and human decisions when faced with changing climate. The response of one species can affect others, for example warmer winters could allow some insect pests to survive in greater numbers, possibly increasing forest defoliation—and consequently, a loss of birds and other animal species—and runoff of materials from the watershed. Furthermore, the changes in vegetation may affect the regional climate itself, for example, through changes in the evapotranspiration, albedo (how an object reflects sunlight), and surface roughness of vegetation. Moreover, organisms influence the concentrations of greenhouse gases in the atmosphere by taking up or releasing carbon dioxide, methane, and nitrous oxide. Partially as a result of this complexity, knowledge of the impacts of climate change on terrestrial resources is less developed and predictions more difficult than for other sectors of the climate impact assessment for Maryland.

Climate change is not new for Maryland's terrestrial ecosystems. During the warming after the last Ice Age, very large changes in the biota occurred, but this was a slow warming that allowed migration and adaptation of plants and animals, unlike the rate of climate change projected over the 21st century. As discussed previously, the mean temperature of the Earth's atmosphere has been relatively stable until warming commenced about 50 years ago. After some basic considerations related to terrestrial ecosystems, in general, this section evaluates the likely impacts of projected climate change on Maryland's agriculture and forests.

**SOME BASIC CONSIDERATIONS**

Before getting to the specifics of the assessment of climate change impacts on Maryland's terrestrial ecosystems, it is useful to consider the complexity of likely responses to climate change, the other human activities that influence these responses, the means of observing changes, and the particular geographic conditions that may influence outcomes.
Responses are complex
Shifts in distribution of terrestrial vegetation of hundreds of miles in eastern North America occurred in association with the 3.6°F increase in global average temperature following the last Ice Age.57 For example, one tree species, Jack Pine, moved about 800 miles north from the southern U.S. to Canada, passing through Maryland at an average of a quarter of a mile per year.58 Numerous studies documenting more recent geographical shifts of the distribution of species toward the poles (in Maryland northwards) and toward higher elevation due to climate warming were summarized in the IPCC Fourth Assessment5 and a recent CCSP synthesis report.59 A small state such as Maryland can expect a greater proportion of its species to be lost to the north and gained from the south than in a larger state. These changes could be beneficial or deleterious. Not all species can adjust successfully. Biomes (broad geographic zones having distinct climates and species) that shift in a quickly warming world are likely to lose a portion of their species complement.59 This loss could also disrupt important ecosystem functions if one or more ecologically important species is lost.

In agriculture and commercial forestry, human skill and knowledge can allow for some adaptation to climate change; for example, by changing crop and plantation tree species, and controlling new pest and diseases artificially. If all else fails, products that can no longer be produced in Maryland economically could be imported from elsewhere. And, other commodities will be produced that are not produced under today’s climate. Some impacts on agriculture and forestry may be seen as beneficial and others would require adaptation but at an increased cost.

A significant and already apparent effect of warming on plants is to hasten the beginning of the growing season and prolong it in the fall. But while a shorter winter and earlier arrival of cherry blossoms may be welcomed, overwintering of plant pests that currently are killed by winter cold could also occur. Heat waves and drought can cause mortality directly through increased stress and reduced growth. Forests which grow more rapidly because of the carbon dioxide fertilization effect—plants require CO₂ for photosynthesis and an increase in atmospheric carbon dioxide can increase growth—may become increasingly fire-prone or subject to insect outbreaks. Animals, both livestock and wildlife, are affected directly by climate and indirectly through changes in the frequency and extent of pest outbreaks, spread of invasive species, animal and plant diseases, extreme weather events, and wildfire.

As ecosystems respond to climate changes, there will be not only changes in species found in

Wicomico County, Maryland, marshlands and forest share waterway with agriculture and development.
Forest cleared for agriculture in one watershed of Maryland’s Coastal Bays.

Maryland and in biodiversity, in general, but also in the ecosystem services they provide. Ecosystem services are the benefits to humans that arise from the functioning of ecosystems, but without deliberate action by humans. These include purification of air and water by plants, decomposition of wastes by microbes, soil renewal, pollination of crops, groundwater recharge by wetlands, maintenance of potentially-useful genetic races, removal of greenhouse gases from the atmosphere by carbon sequestration, and provision for recreation in aesthetically pleasing landscapes.

Land use will affect responses
Climate change is taking place in the context of other rapid changes affecting terrestrial ecosystems, agriculture, and forestry. These include continued exurban development, conversion of natural vegetation to farms and pastures, and changes in air and water quality. Many of these factors affect more than one ecosystem or resource simultaneously and interact with each other, often compounding their individual effects.

An important factor in the response of living organisms to current and future warming that did not exist during the post-glacial warming is the extensive fragmentation of natural landscapes by cities, suburbs, farms, highways, and other features. Some species will be slowed in their northward migration by their requirement for specific habitats of suitable size—habitats that, for these species, are now broken into fragments within an impassable matrix of the human landscape. This will favor species capable of “jump dispersal,” in which a few individuals can reach new, suitable habitats by occasional transport over long distances by wind and water or hitching a ride on vehicles or birds. Some species, such as weedy plants, are more likely to move by jump dispersal; others such as amphibians are very unlikely to do so. Species with very specific habitat requirements and limited dispersal capability, including many plants, may fail to move and could become, at least locally, extinct.

Observing changes is challenging
Our current capacity to observe meteorological and ecological changes is insufficient to provide early indicators and assess the effects of climate change on Maryland’s agriculture, forestry, and terrestrial ecosystems. Meteorological sites on the ground are few in number and limited in the range of measurements they make. The role of these sites in weather forecasting has not been diminished by the development of satellite measurements and computer models; in fact, higher quality observations are required by the models.
Furthermore, ground meteorological stations are irreplaceable for documenting climate variability and change. Studies in other regions have documented changes in the distributions of various plants and animals that are likely the result of recent climate change. Earth resource satellite observations offer a different approach. Satellite data can provide a record of changes in vegetation types and extent, carbon fixation, land cover, and human habitation—all essential components of a climate change monitoring and adaptive management system. While satellite measurements have been made over Maryland for over 30 years, the data have not been systematically acquired and archived. The existing record of crop yields by the National Agricultural Statistics Service (from 1961), the Forest Inventory and Analysis program (from 1953), the Maryland Biological Stream Survey (from 2000), the Breeding Bird Survey (from 1966), and Christmas Bird Count (from 1900) all contribute key information in a period of rapid climate change, but they are alone.

A slice of the regional landscape
Maryland is a cross-section of the Mid-Atlantic, from the eastern Atlantic Coastal Plain to the Appalachian Plateau. Altitude varies from sea level to 3,306 ft. There are substantial differences in climate across the state and within microclimates, such as the rain shadows of western mountains and local effects of ocean breezes. Although the global climate models used in this assessment are too coarse in spatial resolution to reveal all of the patterns of change that may be realized, it should not be forgotten that these changes are superimposed on the substantial cross-state and local differences that already exist.

At Hancock, Maryland, the State narrows to less than two miles from its northern boundary with Pennsylvania to its southern boundary with West Virginia and, even at its widest, Maryland is a relatively narrow slice of the eastern United States. The modest area of the State belies the fact that it crosses the full range of physiographic and climatic regimes of the Mid-Atlantic region and is therefore exceptionally diverse with respect to its area. Its small area also means that the species that may take the places of those unable to compete in a changed climate, including pest species, depend on the conditions in bordering states. Thus, Maryland cannot be separated from its context in a continuum of physiography, climate, geology, soils, and biota extending from Maine to Georgia.

AGRICULTURE
Maryland’s agricultural commodities account for less than one percent of the value of all U.S. commodities, yet agriculture plays an important role in the economy, social fabric, and landscape diversity of the State. Despite the decline in agricultural lands as a result of urbanization, fully one-third of Maryland’s land remains in agricultural land uses. The production of poultry (broilers, turkeys, and eggs) accounts for 36% of the $1.6 billion 2006 value of agricultural commodities, and the corn and soybeans largely grown to feed these birds represents another 17% (Figure 6.1). Horticulture (greenhouse/nursery) accounts for 22% of the value of Maryland’s agricultural output, reflecting the State’s high population density and demand for landscaping and plants.

Crop production
Crop species differ in their critical temperature range for growth and development. Growth and development of a particular crop requires temperatures at some minimum temperature, are fastest at some optimal temperature, and slows down and finally ceases at a temperature maximum. Vegetative development usually has a higher optimum temperature than reproductive development. At elevated temperatures, the life cycle of a grain crop will progress more rapidly but may reduce yield owing to the shorter time available to fill the grain. High temperatures can also result in failure in pollination and grain setting. Yield responses to temperature vary among species based
on the crop's temperature requirements. Plants that have an optimum range at cooler temperatures will exhibit significant decreases in yield as the temperature increases above this range. On its own, the projected increase in mean temperature of 2 to 3°F by 2040-2050 could decrease corn and wheat yields by 8-14% \(^\text{62}\), but may have little effect on soybean yield.\(^\text{63}\) Under the higher emission scenario, toward the end of the century, summer heat stress is likely to be a significant limiting factor in crop production unless there is a transition to new crops or varieties, which may be an expensive proposition for farmers.

Crop development and yield are also affected by the amount of water available in the soil, which is itself affected by elevated temperature. Furthermore, because evapotranspiration increases with temperature, maintaining soil moisture sufficient for germination, growth, and grain setting will be a significant factor in determining the response of crop production to climate change. Despite the mean projection of increased annual precipitation by the climate models, moderate declines in soil moisture are likely to be experienced in summer and fall during the second half of the century under both lower and higher emissions scenarios. Furthermore, rain is likely to be delivered in more intense events, separated by weeks to months with less rain. One has only to recall 2007, a year with relatively high winter and early spring precipitation and a disastrous, weeks-long summer drought as an example of what might occur more frequently. Under these conditions, farmers are likely to increase the use of irrigation—currently, just over 5% of Maryland's crop lands are irrigated—compounding the aquifer drawdown already taking place in some parts of the state (Section 5).

Plant growth is also dependent on the availability of the carbon dioxide required for photosynthesis. Plants respond differently to elevated carbon dioxide concentrations. Cold-season and broad-leaved weeds and cold-season grain crops, including wheat and barley, respond most dramatically to increased carbon dioxide. An increase of carbon dioxide concentrations to 550 ppm could increase the yield of these plants by 10-20\(^\%\), mainly through increased grain production rather than grain size. Corn and many summer weed grasses respond less dramatically to carbon dioxide enrichment, with corn yields increasing less than 10\% given the same increase in carbon dioxide.\(^\text{64}\) However, high temperature stress during reproductive stages can negate the overall carbon dioxide effects on yield even though total plant biomass may increase and attaining even these modest productivity increases requires more fertilizer, unrestricted root growth, and effective control of weeds, insects and disease.\(^\text{7}\)
Under the higher and lower emissions scenarios, atmospheric carbon dioxide concentrations would increase late in the century to 940 ppm and 550 ppm, respectively. By mid-century, a modest 5 to 9% increase in crop yield, except for corn, might be experienced as a result of fertilization. However, under the higher emissions scenario, this effect would diminish as concentrations exceed 600-800 ppm. Deficiencies in soil moisture could further limit yield and require increased irrigation.

While carbon dioxide enrichment can stimulate the production of leafy vegetables such as lettuce, spinach, or radish, their greater leaf area increases their water requirement during the warmest and driest part of the growing season. Some moderation of this effect may be caused by a decrease in plant evapotranspiration as the stomata on the leaves constrict under higher carbon dioxide concentrations, leading to a reduction in water loss and increase in crop yield. This effect, however, is very likely to be small in comparison to the effects of temperature and carbon dioxide fertilization.

Wheat and barley grain and potato tubers contain 10 to 15% less protein when grown under carbon dioxide concentrations of 540 to 958 ppm, diminishing their nutritional value and performance in food processing, for example, producing sufficient gluten for making bread. This effect can be counteracted by providing the plants more nitrogen, but in Maryland that would require more fertilizer, compounding the nutrient pollution problem in the Chesapeake Bay (see Section 8).

Ground level ozone is created on warm days by the reaction of sunlight with nitrogen oxides (NOx) and volatile organic carbon (VOC) compounds, present because of air pollution. Despite efforts to reduce this pollution, Maryland experiences some of the highest ozone in the country. As discussed in more depth in Section 8, warmer temperatures from global warming threatens to increase the concentrations of ground-level ozone and the frequency of high-ozone events. In addition to its effects on human health, ozone is toxic to many plants and particularly to crops such as soybean and wheat. Even mild chronic exposure (40-60 ppb) decreases yield in soybean. However, these effects may be moderated by the reduction in the apertures of plant stomata under elevated carbon dioxide. While the net effects on crop production may be relatively small during the first half of this century, if the pollutant loads of NOx and VOC are not substantially reduced, the added stress of ozone together with heat stress and desiccation are likely to lead to declines in crop production during the second half of the century.

Crop production is affected by competition with weeds. Because the geographic range of many weed species is determined by temperature, climate warming is very likely to lead to a northern shift in the distribution of some economically significant weed species. These include witchweed, cogongrass, and itchgrass that at present are found south of Maryland and the proliferation of invasive kudzu that is already here. On the other hand, some current weed species may become less of a problem. On-going studies in Maryland are showing that weeds grow much faster under higher temperatures and carbon dioxide concentrations likely to be experienced in the next 30 to 50 years—these conditions simulated by experiments conducted in Baltimore. The growth of many weed species is stimulated more by carbon dioxide enrichment than are the cash crops they invade, presenting an additional challenge for weed control.

Beneficial and harmful insects, microbes, and other organisms present in agricultural ecosystems will also respond to climate change. Numerous studies have shown changes in spring arrival, over-wintering, and/or geographic range of several insect and animal species due to climate change. Diseases caused by leaf and root pathogens may increase in Maryland if increases in humidity and frequency of heavy rainfall events occur, but will decrease if more frequent droughts occur.

**Animal production**

For optimum production, livestock require temperatures that do not significantly alter their behavioral or physiological functions needed to
maintain a relatively constant body temperature. As their core body temperatures move outside normal boundaries, animals must begin to conserve or dissipate heat. This reduces the energy available for growth or the production of products such as milk, and ultimately affects reproduction. The onset of heat stress often results in declines in physical activity and eating or grazing. Hormonal changes, triggered by environmental stress, result in changes in cardiac output, blood flow to extremities, and digestion rates. Adverse environmental stress can elicit a panting or shivering response, which increases the baseline energy requirements of the animal and contributes to decreases in productivity. The temperature thresholds of these responses depend on the species in question and the animal's genetics, temperament, and health.

The most important forms of animal production in Maryland are poultry (broilers), comprising 36% of all agricultural cash receipts, and dairy production, comprising over 11% (Figure 6.1). There are no quantitative assessments of the impacts of climate change on poultry production in this State, however housing large numbers of birds with a high metabolism in close quarters already makes them susceptible to heat stress during hot summers, when large numbers of birds can die. To reduce the chance of death requires costly insulation and ventilation of growing sheds. The temperature projections after mid-century, particularly under the higher emissions scenario, will pose a much more serious problem of heat stress on confined poultry production.

The Northeast Climate Impacts Assessment projected little increase in heat stress on dairy cattle and no significant heat-related reductions in milk production for the next several decades. However, under a higher emissions scenario generally similar to the one used here, by mid-century New Jersey and southern Pennsylvania were projected to experience moderate heat stress in July and declines of milk production of up to 12%. By late century, the declines are projected to be 10% under the lower emissions scenario and 15-20% under the higher emissions scenario. Similar or greater declines in dairy production are likely in Maryland.

To maintain levels of production under climate change, livestock producers will select breeds that are genetically adapted to the new, warmer climate. However, breeds that are more heat tolerant are generally less productive.

Climate change is also likely to affect the parasites, pathogens, and disease vectors that affect domesticated animals. Similar effects on pest migration and over-wintering as discussed for cropping systems are likely to be observed for some livestock parasites and pathogens. Also, accelerated development of pathogens and parasites due to the earlier spring and warmer winters is likely.

Warming and associated variation in weather patterns will likely result in more livestock being managed in climate-controlled facilities, even in a more energy-constrained world. Furthermore, agriculture, in general, and the animal production industry, in particular, will surely be under pressure to reduce its greenhouse gas emissions, particularly of methane and nitrous oxide. This could incur additional costs to production, thereby affecting profitability and hence the nature of the agricultural industry in Maryland.

**Summary of impacts on agriculture**

In summary, agriculture in mid-latitude regions
such as Maryland may experience moderate warming benefits in the form of crop and pasture yields under moderate increases in temperature (2-5°F) and increases in atmospheric carbon dioxide and rainfall. However, increased risks of drought in summer and early fall and unknown changes in weed and pest damages will generate uncertainty among farmers and animal producers regarding adaptation to climate change. The warming in the lower emissions scenario during the latter part of this century is projected to have increasingly negative impacts as it approaches or passes the upper end of optimum ranges of different crop and animal species if the higher emissions scenario proves more accurate (Figure 4.3). Therefore, without mitigation of greenhouse gas emissions, the changing climate is likely to pose serious problems for Maryland agriculture resulting from heat stress and summer-fall drought that might increase groundwater demand for crop irrigation.

**FORESTS**

Although Maryland accounts for only 0.3% of the nation’s softwood production and 1.6% of its hardwood production, the forest products industry is economically important in parts of the State, resulting in product output worth $262 million. Paper products account for 60% of that total. Forest products industries employed 9,326 in 2006 and generated $0.4 million in State tax receipts.

**Climate change and forest productivity**

Forest productivity in the United States has generally been increasing slightly since the middle of the 20th century², although there is no assessment specifically for Maryland forests. Forested area has increased dramatically from a minimum at the beginning of the 20th century as areas of the eastern U.S. that had been cleared for agriculture and other purposes have been reclaimed by forests. The potential causes of the increase in productivity include increases in temperature, atmospheric carbon dioxide and nitrogen deposition, but these are difficult to isolate. Temperature, water, and solar radiation are the primary climatic factors that affect forest productivity. Increased precipitation, higher temperature, and a longer growing season will increase productivity where those factors are currently limiting. Consequently, a modest increase in forest yields and regrowth is likely. During the latter part of the century under the higher emissions scenario, however, heat stress and the greater likelihood of summer-fall drought could obviate gains in forest productivity due to global warming earlier in the century. If forest species, such as loblolly pine, currently found farther south, migrate into Maryland or are planted and replace existing species, this could at least partially compensate for some of the lost productivity.

Large departures from typical conditions and extreme events, such as late frosts, drought, and wind storms, can damage or kill trees. The occurrence and severity of such extreme events associated with climate change are projected to increase. These indirect effects of climate on factors such as wildfires and insect outbreaks are likely to contribute to reduction of forest production. The interaction of climate change and these factors could create unprecedented conditions, the effects of which are very difficult to predict. Forests can take decades to re-establish after disturbances are caused by fire, insect outbreaks, and wind and ice storms. These effects are likely to become more important than the direct effects of climate itself in shaping future forest ecosystem structure and functioning. All of these changes will be influenced by the legacy of the logging in the 19th and 20th centuries and the more recent period of fire suppression that has led to dominance by an even-aged community of trees now reaching old age.

**Carbon dioxide fertilization**

As discussed under agriculture, the projected increases in atmospheric carbon dioxide concentration are likely to increase forest growth due to a fertilization effect, but this will depend greatly on the type of forest and its environmental conditions.
conditions. The response of tree growth to elevated CO₂ also depends on the age of the trees; younger trees respond more strongly than older ones. Maryland forests will likely absorb more CO₂ and retain more carbon in wood and soils as atmospheric CO₂ increases, but this will depend on the specifics of how climate changes and on such factors as the age of the forest and the degree of fertilization by nitrogen deposition. These factors are highly relevant when devising strategies to increase forest carbon sequestration for mitigation plans.

**Atmospheric pollution**

Forest growth and dynamics are affected by air pollution in two important ways: the toxic effects of ozone created by emissions of NOx and VOCs from power plants and vehicles, and the stimulatory effects of nitrogen deposited as a result of these NOx emissions. Nitrogen deposition in the eastern U.S. can exceed 10 kg of nitrogen per hectare (or 9 lbs per acre) per year and has increased 10 to 20 times above pre-industrial levels. Although nitrogen deposition has declined recently in Maryland as result of air pollution controls, future emissions are uncertain. Forests are generally limited by nitrogen availability and increased deposition will enhance forest growth. However, if it increases too much, it can have negative effects on forests and on aquatic ecosystems that receive runoff from the forests. The interactions of elevated CO₂, temperature, precipitation, ozone pollution, and nitrogen deposition are likely to be important in determining forest growth and species composition, but the net result of these factors and their interactions is poorly understood. Continued nitrogen deposition on forests can have the result of stimulating the degradation of organic matter in soils by microbes, thus reducing any carbon sequestration resulting from faster growth in a CO₂-enriched world.

**Insect outbreaks**

Outbreaks of forest insects and diseases affect forest composition and production, leading to altered cycles of matter and energy, and changes in biodiversity and ecosystem services. Damage to Maryland forests caused by outbreaks of defoliating insects and other pests cost several million dollars per year. Weather plays an important role in influencing outbreaks of serious forest insect pests, including the gypsy moth, southern pine beetle, hemlock woolly adelgid, spruce budworm, and western spruce budworm. Temperature affects the rate of insect life-cycle development rates, the synchronization of mass attacks that overcome tree defenses, and insect winter mortality rates. Climate also affects the insects indirectly through effects on the host trees. Drought stress, resulting from decreased precipitation and warming, reduces the trees’ ability to resist insect attack.

Outbreaks and expansion of some non-native insect species, such as the hemlock woolly adelgid (Box 6.1), are known to be influenced by climate. The introduced gypsy moth has defoliated millions of acres of Maryland forests. Projections indicate that Maryland’s changing climate is likely to increase the frequency and severity of gypsy moth outbreaks in the future. Longer growing seasons and higher carbon dioxide concentrations might allow forests to recover more quickly after such disturbances. But defoliation disturbances affect carbon uptake, nutrient cycling, and stream hydrology, resulting in the loss of nitrogen from the forest where it is needed, to the Chesapeake Bay where it is harmful.
The hemlock woolly adelgid, an aphid-like insect native to Asia, was first recorded in 1951 in Virginia, and has since spread, causing a severe decline in vitality and survival of eastern hemlock in North American forests (Box Figure 6.1). Once it arrives at a site, complete hemlock mortality is just a matter of time and damaged hemlock stands are replaced by black birch, black oaks, and other hardwoods. While plant biodiversity increases in the canopy and understory, several bird species, including the blue-headed vireo and Blackburnian warbler, have a high affinity for hemlock forests and are at risk as a result of adelgid expansion. Also, changes in the forest canopy affect hydrology and nutrient cycling, resulting in longer periods of dry streams, which, in turn, reduce the abundance of brook trout, brown trout and other fish. Low winter temperatures presently check the spread of the hemlock woolly adelgid, but increasing temperatures and the capacity of the adelgid to develop greater resistance to cold shock indicates that more hemlock forests will succumb in future years.

**Species composition**

As the changing climate after the last Ice Age resulted in the northward shift in the distribution of tree species in eastern North America, 21st century warming will very likely result in the northward shift in the range of trees and forest types currently that exists in Maryland. Trees that need cold winter conditions (for example, sugar maples) or are susceptible to diseases or pests under warmer conditions will retreat northward, possibly replaced by species currently found south of Maryland. Plant hardiness zones for horticultural plants have recently been revised to take account of the changes in the potential ranges of garden plants that have already taken place (Figure 6.2).

By relating the preferred environmental conditions of various forest types to current temperature and precipitation, it has been possible...
to estimate future ranges as climate changes in eastern North America. Under a doubling of CO₂ concentrations—likely to be experienced in the latter half of the century under the low-emissions scenario—the maple-beech-birch forests of Allegany and Garrett counties are likely to disappear, replaced by oak-hickory forests. The oak-hickory forest type that presently characterizes most of the Piedmont and Coastal Plain west of the Chesapeake is likely to transition to an oak-pine forest.

The NECIA concluded that the region’s species would shift northward by as much as 350 miles by the late-century under the lower emissions scenario, and as much as 500 miles under its higher emissions scenario. The NECIA projected that the maple-beech-birch forests that presently characterize most of Pennsylvania would move to northern Pennsylvania, and thus out of Western Maryland, under the lower emissions scenario and retreat to Upstate New York under its higher emissions scenario. In general, then, one would expect that by late-century, Maryland forests would look much like those in eastern Virginia and North Carolina do today, with many more pines.

**Forest ecosystems**

Forests provide many other benefits beyond the lumber and fiber. These ecosystem services, including watershed protection, water quality, flow regulation, wildlife habitat and diversity, climate regulation, carbon storage, air quality, recreational opportunities, and aesthetic fulfillment, are important for the well-being of Marylanders. The market values of few of these ecosystem services have been quantified, but they are nonetheless essential and irreplaceable. All of these services are subject to the direct and indirect effects of climate change as forest productivity and composition changes and disturbance by heat stress, seasonal drought, severe storms, fire, disease, and pest outbreaks increase.

The biodiversity of forest plants, animals, and microbes is also likely to be affected in ways that are difficult to predict let alone quantify. Biodiversity is already being affected at the landscape, species, and genetic levels by a variety of human activities, including habitat loss and fragmentation, invasive species, and air pollution. Climate change poses yet another stress that is likely to reduce biodiversity.

Climate changes have been shown to affect the timing of critical processes of growth and reproduction (for example, flowering and fruiting) in thousands of plant and animal species around the world. These changes can disrupt previously synchronized relationships among species (for example, pollination, prey availability for predators, and food sources for migrant birds). The reduction in population sizes caused by these adverse effects sets the stage for local or global extinctions of species. The American Bird Conservancy estimated that habitat alterations due to climate change may force out 34 or more bird species from Maryland.

The most emblematic of birds that may no longer breed in Maryland because of the unsuitability of habitats is the state bird, the Baltimore oriole. The NECIA also projected that various migratory bird species with northerly or high altitude distributions, including the American goldfinch, purple finch, rose-breasted grosbeak, and black-capped chickadee would experience declines in abundance in the Northeast, while the tufted titmouse, northern cardinal, and indigo bunting have the potential to increase in both range and incidence.

**Summary of impacts on forests**

Maryland forests are likely to experience a modest increase in productivity over the first half of the century as a result of longer growing seasons and elevated atmospheric carbon dioxide concentrations. Later in the century, the composition of Maryland forests is likely to undergo pronounced changes as the maple-beech-birch forests of Western Maryland begin to disappear and pine trees become more prominent in oak-hickory forests of central Maryland. Also, later in the century, heat stress, seasonal droughts, and outbreaks of pests and diseases are likely to diminish forest productivity,
particular under the higher-emissions scenario. This could result in impairment of important ecosystem services that forests provide, including carbon sequestration, control of the water cycle, and maintenance of biodiversity. The extent to which and rate at which other tree species from the south would replace the current species and the services the present forests provide cannot be readily predicted.
COASTAL VULNERABILITY FROM SEA-LEVEL RISE & STORMS

KEY POINTS

> Sea level in Maryland rose by 1 foot in the 20th century, partially because the land is sinking.
  Coastal regions of Maryland have been sinking at about a rate of 6 inches per century and this should continue. Additionally, the average level of the sea in this region rose by about the same amount. As a result, Maryland has experienced considerable shoreline erosion and deterioration of coastal wetlands.

> Sea-level rise is very likely to accelerate, inundating hundreds of square miles of wetlands and land.
  Projections, that include accelerating melting of ice, extend to more than 1 foot by mid-century and 3 feet by late century. If the highest rates are realized under the higher emissions scenario, most tidal wetlands would be lost, about 200 square miles of land would be inundated, and an even greater sea-level rise would occur in subsequent centuries.

> Rains and winds from hurricanes are likely to increase, but their frequency cannot be predicted.
  The destructive potential of Atlantic tropical storms and hurricanes has increased since 1970 in association with warming sea surface temperatures. This trend is likely to continue as ocean waters warm. Whether Maryland will be confronted with more frequent or powerful storms depends on storm tracks that cannot yet be predicted.

MENTION EFFECTS OF CLIMATE CHANGE IN MARYLAND AND MOST PEOPLE WOULD THINK FIRST OF THE THREAT OF COASTAL INUNDATION DUE TO SEA-LEVEL RISE AND THE INCREASED RISKS OF STORM DAMAGE. THE RECORD STORM SURGE FLOODING ASSOCIATED WITH THE PASSAGE OF HURRICANE ISABEL IN 2003 IS STILL FRESH IN THE MINDS OF MARYLANDERS. WITH ITS 3,100 MILES OF TIDAL SHORELINE AND EXTENSIVE LOW-LYING LANDS, ESPECIALLY ON THE EASTERN SHORE, MARYLAND'S COASTAL ZONE IS PARTICULARLY VULNERABLE TO CLIMATE CHANGE. INDEED, THE CENTRAL CHARGE TO THE ADAPTATION AND RESPONSE WORKING GROUP OF THE COMMISSION ON CLIMATE CHANGE IS TO “RECOMMEND STRATEGIES FOR REDUCING THE VULNERABILITY OF THE STATE'S COASTAL, NATURAL, AND CULTURAL RESOURCES AND COMMUNITIES TO THE IMPACTS OF CLIMATE CHANGE, WITH AN INITIAL FOCUS ON SEA-LEVEL RISE AND COASTAL HAZARDS (E.G., SHORE EROSION, COASTAL FLOODING).” THE COMMISSION IS THEREFORE CHARGED WITH DEVELOPING APPROPRIATE GUIDANCE TO ASSIST THE STATE AND LOCAL GOVERNMENTS WITH IDENTIFYING SPECIFIC MEASURES (E.G., LOCAL LAND USE REGULATIONS AND ORDINANCES) TO ADAPT TO SEA-LEVEL RISE AND INCREASING COASTAL HAZARDS.

This section explores what we know about sea-level rise in Maryland and the Chesapeake Bay region, and applies the latest models and scientific results that provide insights into the sea-level rise that may be experienced during the present century and beyond. Projections are made for the higher and lower emission scenarios as has been done for temperature and precipitation in Section 3. The section further explores current scientific knowledge of the likely consequences of global warming for extratropical storms, such as Nor'easters, and the tropical cyclones that we know as hurricanes. The potential impacts on tidal wetlands, coastal lands and development, and storm surges are then evaluated.

SEAS RISING OR LAND SINKING?

As mentioned in Section 1, sea level rose rapidly as glaciers melted after the peak of the last Ice Age 20,000 years ago. At that time, the Atlantic shoreline was near the edge of the continental shelf, more than 80 miles off Ocean City, and the rivers ran across
the present shelf to the sea. By 8,000 years ago, sea level had risen to the point of flooding the lower Susquehanna River valley, creating a tidal estuary, the nascent Chesapeake Bay (Figure 7.1).\(^3\) The rate of sea-level rise during this period of rapid melting of glaciers was about 16 mm/year. (Throughout this discussion, metric units are used for annual rates to facilitate presentation and calculation, but rates over longer periods are converted to feet for ease in comprehension.) By 5,000 years ago, the rise of the ocean virtually ceased, but the Bay continued to deepen and expand, filling the lower valleys of the Potomac, Patuxent, Patapsco, Choptank, and other rivers. This was because the land was sinking as the bulging of the Earth's surface, resulting from the tremendous burden on the crust by the very thick glaciers that occupied what is now Hudson Bay and Quebec, subsided. This rate of subsidence was relatively rapid initially, but continues to this day as a slow-motion rebounding of an event that peaked 20,000 years ago.

Because different coastlines around the world are sinking at different rates—or actively rising in some previously glaciated or geologically active regions—sea-level rise experienced at specific places will differ, even with a comparable rising of the level of the ocean itself. It is, then, appropriate to refer to “relative sea-level rise”—the water level relative to the land at that place. This is typically estimated by tide gauges that have long been fixed in place. The tide gauge record for Baltimore, which is one of the nation’s longest, shows that the water levels there are highly variable as a result of weather events, strong seasonal variations, and longer oscillations in the North Atlantic Basin. On the average, however, relative sea level increased approximately one foot over the 20th century (Figure 7.2). Note, however, that for the first 30 years of the record the rate of relative sea-level rise was slower, with a disproportionate part of the rise in the mean level coming since 1930.

Analysis of many such tide gauge records from around the world, including those from more geologically stable locations, allowed the IPCC to conclude that the global mean sea-level rise, once the effects of land subsidence or emergence are removed, was approximately 1.8 mm/year between 1961 and 1993.\(^2\) Relative sea level at Baltimore rose at a rate of about 3.5 mm/year, indicating the local rate of subsidence was 1.7 mm/year or roughly half a foot per century. The effects of regional land subsidence on relative sea-level rise is apparent
SECTION 7: COASTAL VULNERABILITY FROM SEA-LEVEL RISE & STORMS

Relative Sea-level Rise is a Combination of Sea-level Rise and Land Subsidence

Factors Associated with:
1. Steric (thermal) expansion of seawater with warmer temperatures
2. Increasing runoff from melting continental glaciers with warmer temperatures
3. Increased rate of mid-ocean ridge spreading (decreases the volume of the ocean basin)

Land Subsidence
4. Compression of surface sediment layers
5. Compression of deeper layers due to groundwater extraction
6. Collapse of mantle forebulge with retreat of continental glacier
7. Regional subsidence of a tectonic plate
8. Depression of the continental margin by weight of sediment and seawater

And on longer timescales (hundreds of thousands to millions of years):

- Regional subsidence of a tectonic plate
- Depression of the continental margin by weight of sediment and seawater
- Increased rate of mid-ocean ridge spreading (decreases the volume of the ocean basin)

Results in:
- Coastal Flooding

by comparing tide gauge observations along the Atlantic coast (Figure 7.3). Glaciated areas to the north experienced less relative sea-level rise than those located in the glacial forebulge region that are still subsiding. This subsidence (reflected by the difference between relative sea-level rise and the global mean) diminishes to the south of the Chesapeake Bay region. Note, however, that subsidence rates vary within the Bay region, with Hampton Roads (Norfolk) experiencing a relative sea-level rise of 4.2 mm/year. This is likely the result of groundwater extraction from permeable rock or sediments, which can cause localized subsidence of the ground surface. Similar localized areas of greater subsidence resulting from large groundwater withdrawal may exist around Solomons and Cambridge, Maryland. However, for the Chesapeake Bay as a whole, the relative sea-level rise of about one foot during the 20th century resulted from near equal parts of subsidence and global sea-level rise. And, there is no reason to expect that the regional forebulge subsidence, which is in the process of adjusting over thousands of years, will be different than what was observed over the past century.

GLOBAL SEA-LEVEL RISE

The limited records available indicate that global sea level, adjusted for land movements, was nearly stable during the 19th century but began to increase around the turn of the century and then accelerate from the 1930s onward (Figure 7.4). Based on tide gauge data, the mean rate of sea-level rise was estimated by the IPCC to have been 1.8 mm/year between 1961-2003. Since late 1992, there have been satellites deployed with the capability of very
accurately measuring their altitude over the ocean's surface. Large numbers of measurements can be averaged over a 10-day period to develop precise maps of the surface of the ocean. Based on analysis changes in the ocean's elevation between 1993 and 2003, the IPCC noted a global average of 3.1 mm/year (black line in Figure 7.4), although the level of various regions of the ocean changed at different rates. While the degree to which the differences with sea-level rise estimates derived from tide gauges represent methodological differences or an actual acceleration of the rate of global sea-level rise has not been fully resolved, such an acceleration is consistent with the observed warming of the ocean surface and melting of glaciers, both of which expand the ocean's volume (Figure 7.5).

Sea-level rise during the recent past is caused primarily by expansion of the volume of the warming ocean and, secondly, by the observed melting of glaciers and ice caps. The melting of the massive polar ice sheets on Greenland and western Antarctica were only a small component of sea-level rise, although the contribution of Greenland seems to be growing. It is unlikely that the total melting of the Greenland Ice Sheet would occur this century and produce the kind of 25-foot inundations seen in popular dramatizations of sea-level rise, although this could happen sometime in the future.

**FUTURE SEA-LEVEL RISE**

How much sea-level rise will Maryland experience over the coming century in a warming climate? The IPCC projected that global sea level would rise by 7 to 15 inches under the lower emissions (B1) scenario and 9 to 20 inches under the higher emissions (A2) scenario, although the IPCC specifically stated that these projections cannot "provide a best estimate or an upper bound for sea-level rise." Adding to those projections the expectation that land subsidence in coastal Maryland would continue at the rate observed during the 20th century yields the relative sea-level rise projections labeled as IPCC projections in Figure 7.6. These projections suggest that Maryland would experience a rise in sea level ranging from just slightly more than the one foot experienced during the past century to more than twice that amount. However, the IPCC sea-level rise projections have been widely criticized as too conservative because they do not account for rapid changes in ice flow that could be experienced.

---

**Figure 7.4**: IPCC compilation of global data since 1870 shows acceleration of sea-level rise during the 20th century. The blue curve shows coastal tide gauge measurements since 1950 and the black curve is based on satellite altimetry.

**Figure 7.5**: The IPCC attempted to estimate the factors responsible for increasing the ocean's volume, including thermal expansion and melting of glaciers and polar ice sheets. These are compared with the global mean (dot) and range of observed sea-level rise. These estimates come closer to explaining the higher rates of sea-level rise based on satellite observations during 1993-2003.

**Figure 7.6**: Projected relative sea-level rise in Maryland during the 21st century under the higher and lower emissions scenarios.
The IPCC readily admitted that such effects were excluded because these ice flow dynamics could not reliably be modeled when its Fourth Assessment was being prepared and cautioned that sea-level rise could be higher as a result.

The melting of ice floating on the sea has no effect on sea level, much as ice cubes melting in a glass do not cause the glass to overflow. But, how much higher could sea-level rise if losses of ice that rests on land accelerate? This was estimated by examining three scientific reports appearing since the publication of the IPCC Fourth Assessment. They projected potential 21st century sea-level rise using three different methods. One used a statistical approach relating sea-level rise to observed temperature increase; another assumed that the continuation of the rate of recently observed acceleration of ice loss, primarily from glaciers and ice sheets; and a third estimated an upper limit of ice sheet contribution during the 21st century in projecting sea-level rise in the state of Washington. The statistical model projected a mean increase of 3.4 inches in global sea level under the higher emissions (A2) scenario, compared to the IPCC projection of 9 to 20 inches. A word of caution, though, in that the statistical range of possibilities extended to 47 inches in the range of scenarios tested. Remarkably, the other two studies produced estimates of accelerated melting that, when added to the IPCC projections, resulted in very similar global sea-level rise at the end of the century under the higher emissions scenario. When coastal Maryland subsidence rates are taken into account, the additional relative sea-level rise based on the assumptions of these studies is represented in Figure 7.6 by the lighter-colored extensions above the darker-colored boxes that represent the IPCC projections. This suggests a sea-level increase of as little as 0.6 feet (probably unlikely because this is scarcely above the 20th century rate) to much as 1.3 feet could be experienced along the Maryland’s coast by the middle of the century. By the end of the century, accelerated melting could produce a relative sea-level rise from 2.7 feet under the lower emissions scenario to 3.4 feet under the higher emissions scenario.

These adjusted estimates based on the IPCC projections should not be considered as model forecasts, but as reasonable bases for assessment and...
planning that take account of the admitted high-end uncertainties in estimating future sea levels. They do not consider the upper bounds of the confidence limits presented in the statistical study, but can be used with confidence in concluding that it is likely that Maryland will experience sea-level rise of 2 feet by the end of the century. Further, this estimation indicates that, at this time, there is no scientific basis for projecting sea level rise of more than 4 feet during this century. Of course, sea-level rise will not stop at the end of the century and an important difference between the higher and lower emissions scenarios is that the higher emissions scenario is much more likely to move global temperatures over a threshold that would lead to the irreversible melt down of at least the Greenland Ice sheet, that would result, during succeeding centuries, in the 25-foot inundation of cities depicted in some frightening animations.

**COASTAL WETLANDS**

This section assesses the impacts of sea-level rise on shorelines and low lying lands. Section 8 will further explore the consequences of sea-level rise on the Chesapeake Bay and Maryland’s Coastal Bays. An important part of these coastal ecosystems is, however, the coastal wetlands that fringe the estuaries. Maryland has some 200,000 to 285,000 acres of coastal wetlands that provide critical nursery grounds for commercially important fisheries, important feeding grounds for migratory waterfowl, and home to furbearers and other wildlife. These wetlands buffer shorelines from erosion during storms, trap sediments and associated nutrients and pollutants, and provide a variety of outdoor recreational opportunities, such as sport fishing, hunting, kayaking, and bird-watching. The quantity and quality of these resources and opportunities available for future generations of Maryland residents will be directly affected by climate change.

Tidal wetlands will persist only if they build vertically through the accumulation in their soils of mineral (sand, silt, clay) and organic (plant material, especially plant roots) matter at a pace equal to or greater than sea-level rise—otherwise they will become submerged and convert to shallow open water habitat. In addition, given the generally shallow slopes over much of the Maryland coastal zone, those tidal wetlands that are able to keep pace with sea level will migrate and expand inland, but only so long as there are no barriers to migration (such as shore stabilization structures, houses, and roads).

As sea level rises, the fate of coastal wetlands in Maryland will be determined largely by how the needed build-up of soils is impacted by natural processes, human activities, and the effects of the changing climate. Changes in the river runoff and shoreline erosion would affect the mineral sediment available for soils. Droughts could affect the accumulation of organic matter. More intense storms and greater storm surge could erode wetlands, but also transport mineral sediments onto the wetlands.
and affect accumulation of organic matter by the negative effects of salt-water intrusion on plant growth.

Wetland survival during sea-level rise will vary among coastal wetlands depending on their location and the degree to which they are able to build up the soil surface. Marshes behind barrier islands on the seaside Eastern Shore increase their soil level vertically primarily as a result of sand driven over the islands during storms. An increase of storm intensity or frequency could build and expand the marshes as sea levels rise. Estuarine marshes depend more on organic matter and fine-grained resuspended sediments to build their soils. Without some significant source of mineral sediments such as discharge from a river, organic soils can only build so fast to keep up with sea level rise—beyond some threshold, the marshes begin to deteriorate as plants die because their roots become continuously inundated and wetlands convert to shallow ponds.

As sea level has risen in the Chesapeake Bay, the gradual inundation of the low lying land on the lower Eastern Shore has led to the formation of tidal marshes that are built atop submerged uplands, particularly in Dorchester and Somerset counties. Accretion rates in these marshes are typically less than the current rate of sea-level rise. At the Blackwater National Wildlife Refuge, land surface adjustments related to shallow soil subsidence and possibly to groundwater withdrawal have locally increased the rate of relative sea-level rise, contributing to severe wetland loss. In addition, the effect of local stressors on vegetation growth, including intense herbivory by nutria, burning of the marsh for wildlife management, and altered flooding and salinity patterns related to roads and other construction activities, may be limiting soil buildup needed to counteract sea-level rise, which contributes to severe wetland loss.

If sea level were to rise at 6 mm/year, most of the remaining wetlands would be converted to open water (Figure 7.7). Marsh elevation is not accreting appreciably under present rates of sea-level rise. Consequently, it is unlikely that these marshes could build additional soil to keep pace without some external sediment subsidy. The placement of sediment dredged from channel maintenance in the Chesapeake Bay is currently under evaluation as a way to sustain these drowning wetlands.

Coastal responses to accelerated sea-level rise are difficult to predict over an area as large as Maryland, but a panel of wetland experts considered existing knowledge of responses and likely climate changes to project wetland survival for the Chesapeake Bay and Coastal Bays during this century. Three relative sea-level rise scenarios were evaluated: 3 mm/year (approximating the current rate), 5 mm/year, and 10 mm/year. The fate of the wetlands was assigned to one of three possible outcomes: keeping pace, marginal (able to maintain elevation under optimal conditions, and loss (flood to the point of loss of Intensive development and the loss of marsh impact the health of Maryland's Coastal Bays.
emergent vegetation). The findings summarized below are intended to provide a regional perspective and should not be applied to site-specific cases:

- **For the Maryland Coastal Bays**: marshes are able to keep pace with 3 mm/year of sea-level rise; at 5 mm/year, their ability to do this would be marginal and depend on the frequency of storms to mobilize and deliver sediments; and, at 10 mm/year, there would be marsh loss to shallow open water.

- **For the Chesapeake Bay**: estuarine marshes on the lower Eastern Shore are already experiencing high rates of loss and their survival is considered marginal at 3 mm/year and subject to substantial loss under either of the accelerated rates; estuarine marshes in the northern portion of Chesapeake Bay and on the western shore are keeping pace with 3 mm/year, but would be marginal at 5 mm/year and subject to loss at 10 mm/year; and, tidal freshwater marshes and swamps accumulate both mineral sediment and large quantities of plant organic and are considered sustainable under accelerated sea-level rise assuming salinities do not increase and sediment supplies are maintained.

To put these expert judgments in the context of the sea-level rise projections under the higher and lower emissions scenarios (Figure 7.6), based on the IPCC projections, the rate of sea-level rise over the first half of the century is likely to range from 3.5 to 5.8 mm/year, with the average for the higher emissions scenario 4.7 mm/year versus 3.8 mm/year under the lower emissions scenario. Except in tidal freshwater environments or where there is a significant supply of mineral sediments, the survivability of coastal wetlands is likely to be marginal, at least under the higher emissions scenario.

During the second half of the century, sea level is projected to rise, based on the IPCC, by an average of 4.8 mm/year under the lower emissions scenario versus 5.7 mm/year under the higher emissions scenario, however, the upper end of the range under higher emissions is 7.8 mm/year. Consequently, the difference in the path of global emissions of greenhouse gases is likely to determine whether there is marginal survivability of at least some of Maryland’s tidal wetlands and the predominance of wetland loss. However, with accelerated melting, the rate of sea-level rise could exceed 10 mm/year by the middle of the century, resulting in loss of the substantial majority of Maryland’s 430 square miles of tidal wetlands. While some new tidal wetlands will be created over land that is presently dry, the dry land and nontidal wetlands potentially available for inland migration is only about 10% of the area of existing tidal wetlands.

A recently completed, parallel analysis by the National Wildlife Federation also projected losses of a majority of the brackish marshes, tidal swamps, and estuarine beaches in the Chesapeake Bay under a 27-inch rise in sea level by the end of the century. Clearly, the intertidal habitats that are important to the characteristics and productivity of the Chesapeake Bay ecosystem are at risk as a consequence of global warming.

### EROSION & INUNDATION

In addition to causing the deterioration and landward migration of coastal wetlands, projected sea-level rise will cause the erosion and retreat of shorelines and, ultimately, the inundation of presently dry land. Based on general estimates derived from the Maryland Department of Natural Resources airborne surveys using a highly accurate laser instrument called LIDAR (Figure 7.8), it is roughly estimated that over 180 square miles of land would be inundated by the end of the century under the higher emissions scenario, assuming the

**Potential Inundation on Maryland’s Eastern Shore**

![Image](https://example.com/image.png)

Figure 7.8. Extensive areas of wetlands and low-lying lands less than 2 feet above mean sea level (light blue) are likely to be inundated this century. Lands with elevations between 2 and 5 feet (medium blue) are also potentially at risk. Image based on aircraft LIDAR mapping by the Maryland Department of Natural Resources.
higher sea level rise rates driven by accelerated ice melting (Figure 7.6). If the growth of greenhouse gas emissions is not mitigated, the inundation of land could be more than 60% if the growth of emissions were reversed by mid century, based on comparison of sea-level rise projections under higher and lower emission scenarios. The extent of inundation of dry lands will, of course, be dependent on steps taken to respond to rising sea level, but these estimates reflect the amount of present land that will be below the level of normal spring high tides. One has to also keep in mind that as sea level rises, the volume of the Chesapeake Bay will increase and this will affect the normal range of the tides, in general, making the high tides a little higher (see Section 8).

Most of the land subject to inundation is naturally located in the lowest lying parts of the State, notably along the Chesapeake Bay side of the lower Eastern Shore in Dorchester, Wicomico, and Somerset counties (Figure 7.8). Several islands (including Smith Island) and necks in this region, some inhabited, may be completely inundated or cut off within this century. Outside of this region, parts of Talbot, St. Mary’s, Anne Arundel, and Baltimore counties are similarly susceptible. Assuming the projection included accelerated melting (resulting in sea-level rise to just over 3 feet; Figure 7.6), the homes of thousands of Marylanders would be lost. With a relative sea-level rise of just half that, which should be regarded as likely within the century, 264 miles of roadway, 226 miles of rail line, and 31% of the port facilities in Maryland would be at risk of inundation.

In addition to inundation, of course, substantial shoreline erosion will very likely occur, but the distance of shoreline retreat will vary greatly by location, depending on the land forms, soils, exposure, structural protection, and other factors. Even shorelines characterized by high bluffs are susceptible to retreat due to undermining and slope failure. The barrier islands of Maryland’s ocean shore already experience morphological changes through erosion and overwash. If sea-level rise accelerated to 5 mm/year, as projected under the higher emissions scenario sometime during the middle of the century, it is very likely that northern Assateague Island, south of Ocean City, would fragment with one or more new inlets opening to the Coastal Bays.95 This would dramatically impact not only this National Seashore but also the Coastal Bays, by exposure to waves and storm surge.

**STORMY WEATHER AHEAD?**

The relationship between climate change and storms has received much attention after the devastation of Hurricane Katrina in 2005, which produced record storm surge and property loss and awakened the nation to its vulnerability. This relationship has been hotly debated within the scientific community, but another U.S. Climate Change Science Program (CCSP) synthesis report recently provided a consensus perspective based on the latest scientific results and analysis.13 The Atlantic tropical storm and hurricane destructive potential increased since 1970 in association with warming Atlantic sea surface temperatures. And, it is likely that the annual numbers of tropical storms, hurricanes, and named hurricanes increased over the past 100 years during which the sea surface temperatures also increased. Also, it is very likely that the increase of greenhouse gases contributed to this ocean warming. The CCSP synthesis concluded that it is likely that hurricane rainfall and wind speeds will increase in response to global warming, but could not predict any change in frequency in hurricanes during this century. Two
very recent studies have actually projected a decrease in hurricane and tropical storm frequency, but an increase in their wind intensity and rainfall.96

There has been a northward shift in the tracks of strong non-tropical storms, such as Nor’easters, but evidence is inconclusive in the Atlantic to draw conclusions about the strength of these storms. The CCSP synthesis concluded that there are likely to be more frequent strong non-tropical storms, with stronger winds and more extreme wave heights.

The degree to which Maryland will be confronted with more frequent or powerful storms depends heavily on the storm tracks, which scientists are not yet able to predict for future decades. However, because of the above projections of storm intensification and because hurricanes will be able to travel farther north as a result of the warming sea surface conditions, it is likely that Maryland will experience more powerful hurricanes or tropical storms and more powerful and frequent non-tropical storms than in the 20th century. It is not now possible, however, to quantify this increased risk.

While more intense storms (for example, with higher wind velocity and greater precipitation) generally produce greater storm surge (raising of the water level by high winds and reduced atmospheric pressure), the storm surge experienced depends greatly on the size, approach, and speed of the storm. For example, Hurricane Katrina produced much higher storm surge along the Mississippi Gulf Coast than Hurricane Camille, which hit more or less the same area with higher winds. Hurricane Isabel in 2003 produced record storm surges throughout much of the Chesapeake Bay because its path carried it up the western side of the Bay, with its counterclockwise winds driving water north all the way.97 But, its storm surge was higher by about one foot than a large storm with a similar track that hit in the 1930s—the difference being the relative sea-level rise that had taken place since then (Figure 7.2). This means that assessments of future vulnerability to storm surges must take into account both the moving baseline of sea-level rise and the greater potential of more intense storms.
In many respects, the Chesapeake Bay defines Maryland, extending through the center of the state, providing abundant resources, rich cultures, a port to the world, and commanding a major commitment for its protection and restoration. The changing climate will have multiple and complex effects on the Chesapeake Bay as well as on Maryland’s Coastal Bays and the nearshore ocean environment. Warming of water temperatures throughout the year, earlier warming and later cooling, changes in precipitation and freshwater runoff, sea-level rise, and stronger winds and tropical and non-tropical storms will affect these coastal ecosystems and economies, including navigation, energy, tourism, and fishing industries. As discussed in the previous section, sea-level rise is very likely to have major consequences for coastal wetlands and shorelines, but will also deepen the bays, affecting both water circulation and biota.

Climate change will complicate the effects of nutrient pollution, the reduction of which is a central objective of the restoration and protection of the bays. Milder winters could lead to increased disease and parasitism in coastal living resources and changes in the species able to live here. Not all effects on Maryland’s coastal ecosystems and industries will necessarily be negative. Shorter winters could mean longer growth seasons for blue crabs and improved fishery yields. Reductions in the frequency of ice formation could allow oysters to grow along shorelines and in very shallow water, much as they do in South and North Carolina.

The projected changes in temperature, precipitation, droughts, and floods that would affect coastal ecosystems during the century are described in Section 4; the likely consequences of global climate change on sea levels and storm intensity are described in Section 7. It is very likely that temperature and sea level will increase with the limits projected in Figures 4.2 and 7.6, respectively. For the reasons discussed in Section 4, there is less confidence in the trends and extent of precipitation and runoff.

Moving the Chesapeake Bay south along the coast as depicted in Figure 4.7 is a way to put the warming of the Bay in context. The Bay is displaced by matching the projected future Bay summer-fall temperatures with those presently experienced in estuarine waters to the south.98 Warming by 2050 under either emissions scenario is likely to change seasonal temperatures to those currently experienced in North Carolina estuaries. The emissions scenarios would make a big difference
by the end of the century, however, with conditions approximating present day southern North Carolina under the lower emissions scenario but south Florida under the high emissions scenario!

But, the vision of the future Chesapeake Bay harboring shrimp and alligators should be counter-balanced with caution. Warming will likely not geographically shift ecosystems; the Chesapeake is not likely to be just like Pamlico Sound by the middle of the century, harboring the exact same fish, plants, and animals and supporting similar coastal industries. Rather, changes in these ecosystems cannot be fully predicted and will probably yield novel species combinations, ecosystem adjustments, and mixes of living resources. Differences in the physical environment (for example, tidal range) will continue and changes in river flows and salinity will also affect the future ecosystems. Furthermore, geographic barriers may exist for more southern species to invade the Chesapeake Bay as conditions favor their colonization and native species could adapt to new conditions if they occur gradually.

**NUTRIENT POLLUTION**

Over-enrichment by human nutrient inputs, or eutrophication, has degraded the entire Chesapeake Bay ecosystem in pervasive ways, and reducing nutrient pollution is the lynchpin of the Chesapeake Bay Program. The Chesapeake 2000 Agreement commits the Bay states and federal government to reduce nutrient inputs in order to restore the quality of tidal waters sufficient to remove them from their listing as impaired, and this was determined to require a 48% reduction of nitrogen loading and a 53% of phosphorus loading, derived from a 1985 base load. Reducing and controlling eutrophication is also a central management objective for the Coastal Bays. While nutrients are essential for productive estuaries, excess nutrients contribute to reduced water clarity, loss of submerged vegetation, and low oxygen in bottom waters during summer months (hypoxia or so-called “dead zones”; Figure 8.1). By affecting temperature, precipitation and runoff, sea level and winds, and possibly nutrient loading, climate change will affect the capacity of Maryland’s estuaries to assimilate nutrients and recover from eutrophication.

**River flows, nutrients, and hypoxia**

Freshwater inflows into the Chesapeake Bay affect salinity and circulation and, thereby, the distribution of organisms and the functioning of the ecosystem. Freshwater inflow typically peaks during the spring as snow melts and precipitation increases. The spring flow delivers a pulse of nutrients that, along with light and rising temperatures, fuels a bloom of microscopic planktonic algae, particularly diatoms, in the upper- to mid-Bay. The spring...
phytoplankton bloom, maintained by the nutrient input and sufficient mixing of the water column, is largely not consumed by zooplankton. Most of the biomass produced sinks to the bottom where it is eventually decomposed by bacteria as temperatures warm toward the summer. The respiration of bacteria consumes dissolved oxygen, which is not replenished by mixing because the bottom water is cooler and saltier, and therefore denser. This density stratification prevents reoxygenation of bottom waters, but when mixing events occur, the nutrients released by microbial decomposition stimulates more algal blooms, thus continuing a vicious cycle that maintains hypoxic (low oxygen) or anoxic (no oxygen) conditions.

Climate models project increasing winter temperatures (by an average of 4 and 7°F for lower and higher emissions scenarios, respectively; Figure 4.2) and rainfall (by about 10-13% under either scenario; Figure 4.8) over the century for Maryland. On the other hand, warming over the Susquehanna River Basin is very likely to reduce the storage of water in the form of snow in the watershed and therefore even out the inflows to the Bay during the winter-summer period. A reduction in the peak spring inflows could result in a reduced spring phytoplankton bloom as nutrients would be delivered more evenly over the winter and spring. Warmer winter temperatures could cause an earlier occurrence of a smaller spring bloom centered in the upper Chesapeake Bay.

These outcomes are largely speculative and based on understanding of recent conditions, but illustrate the complexity of the physical, chemical, and biological processes that regulate the production of organic matter in the nutrient-enriched Chesapeake Bay. Of course, these processes will also be subject to change as the climate changes. Temperature increases affect the production of phytoplankton biomass and the grazing of this

Dead zones are likely to expand with higher temperatures and precipitation

An excess of nutrients can lead to large algal blooms that cover shorelines.

Stormwater runoff from roads and parking lots enter Maryland waterways.
biomass by zooplankton.\textsuperscript{102} A reduction in winter-spring phytoplankton biomass has been observed in Narragansett Bay, Rhode Island, during unusually warm winters.\textsuperscript{103} In particular, and potentially quite significantly, if relative sea level were to increase by as much as 3 feet, as considered in Section 7, the volume of the Chesapeake Bay would increase by about 14\%, shifting the salinity gradient, changing physical processes resulting from mixing of fresh and ocean water, and increasing the volume of bottom waters susceptible to hypoxia.

In spite of this complexity, climate change is likely to exacerbate hypoxia. Warmer waters can hold less oxygen to begin with, delivery of nutrients from the watershed would increase with increased precipitation and runoff, and salinity decreases and temperature increases may increase density stratification between surface and bottom waters. Considering these facts, it is more likely than not that hypoxia will worsen as a result of 21st century climate change unless greater reductions in nutrient loading are achieved and sustained.\textsuperscript{104,105}

**Harmful algal blooms**

Harmful algal blooms (HABs) are a growing problem affecting aquatic ecosystems worldwide, including the Chesapeake Bay.\textsuperscript{106} These blooms yield high densities of algae that negatively affect other organisms or produce toxins harmful to animals.\textsuperscript{107} Humans may be affected by HAB toxins either through direct exposure or by consumption of seafood containing the toxins. The Chesapeake Bay and the Coastal Bays are home to several potential HAB-forming species, including dinoflagellates (e.g., *Pfiesteria piscicida*, *Prorocentrum minimum*, *Karlodinium micrum*), a raphidophyte (*Heterosigma akashiwo*) and a cyanobacterium (*Microcystis aeruginosa*).\textsuperscript{108} HABs are commonly associated with nutrient over-enrichment, although many other factors affect their occurrence and prevalence. Some species of harmful dinoflagellates, such as *Prorocentrum*, and cyanobacteria (blue green algae) seem to be favored and grow faster under high temperature.\textsuperscript{109}

Climate change is very likely to produce warm surface water temperatures and prolonged density stratification between surface and bottom waters conditions that favor dinoflagellate and blue green algal species, some of which are HAB-forming. But without more specific evidence and consideration of other moderating effects, such as predators and competitors, it is not possible to conclude that HABs will increase as a result of warmer temperatures alone. Nutrient inputs will remain the key factor in controlling algal blooms in the warmer bays.

**Habitat squeeze**

The high oxygen requirements for respiration under high temperatures and expansive dead zones act to reduce the habitats that can be used by fish such as striped bass, or rockfish as they are locally known. These factors may co-occur to the point of acute stress and fish kills, which already occur with some frequency in the Chesapeake Bay and in poorly flushed tidal creeks and canals in the Coastal Bays. Alternatively, the fish might swim away to avoid the stressful conditions in what might otherwise be preferred habitats. This can lead to increased risk of predation and capture by fishers or to increased competition within the reduced, remaining habitat (Figure 8.2). The high densities of fish in the few
remaining suitable areas can also increase the risk of disease and parasitic infection or infestation, contributing additional stress to a fish that is already behaving, feeding and growing below par. Habitat squeezes in the Chesapeake Bay due to the degraded water quality and warming temperatures since 1950 may have already contributed to local extinctions of sturgeons, which are among the least tolerant Chesapeake Bay species to hypoxic summertime conditions.

**Management implications**

Although still far from reaching the restoration goals for the Chesapeake Bay, considerable reduction of nitrogen and phosphorus loads to the Bay has been accomplished though large public investments in waste treatment facilities and land management practices to reduce the runoff of nutrients. In addition to effects that climate change might have on hypoxia, harmful algal blooms, and habitat suitability, it could affect agricultural practices and forest health, and increase the frequency of flooding in ways that deliver more nutrients to the estuaries and worsen the symptoms of eutrophication as well as cause additional challenges in those sectors. If this happens, nutrient loads would have to be reduced beyond current targets in order to meet the water quality need to restore living resources.

**ESTUARINE SEDIMENTS**

The sediment that lines both the shoreline and the bottom of Chesapeake Bay and the Coastal Bays also shapes the varied habitats of its productive ecosystem. If this sediment remains on the shore or on the bottom and if inflowing rivers run clear, then the clarity and productivity of the Bay’s waters are only limited by the nutrient supply and perhaps the stratification. However, if sediment is stirred into these waters, by waves, currents, and their associated turbulence, or delivered by muddy rivers, then it may deprive submerged vegetation of needed light, deprive oysters their ability to sustain viable reefs in the face of siltation, and alter the foraging or predation of animals dependent on visual cues. Because a portion of the bottom sediment is easily erodible, estuarine circulation creates a zone of maximum turbidity near the head of Chesapeake Bay. Although this turbidity maximum is confined to a limited reach of the estuary, it constitutes an ecosystem crucial to early life stages of important fisheries.

Over geological time, estuaries are ephemeral

A plume of sediment, possibly from an adjacent construction site, fills a river.
features, ultimately losing the battle between sea-level rise which acts to create them and the movement of sediment off the land to fill their shallow depths. With the slowing of the rise of sea level 5,000 years ago (Figure 7.1), despite the fact that land subsidence was still raising the water levels, the filling of the Chesapeake Bay with sediments was also occurring, both from the head with sediments coming down the Susquehanna and the other great rivers and from the mouth with sand transported into the mouth of the Bay from the continental shelf. Land clearing during the 17th and 18th centuries resulted in large influx of sediments, filling in many smaller tributaries that were navigable during the colonial period. Continued relative sea-level rise a century ago, dominated by the sinking of the land rather than the rising of the ocean (see Section 7), eroded shorelines and upland deposits, bringing more sediments into the estuary. The gradual disappearance of Chesapeake Bay islands provides a graphic testament to this progression.112

The processes that control delivery of sediment to the Bay’s waters—shoreline erosion, resuspension, or erosion in the watershed and subsequent delivery by rivers—are, in turn, controlled by the weather. As in other bodies of water, sediment transport in the Bay and its watershed occurs as a comparatively slow, inexorable process occasionally punctuated by episodes of wholesale erosion and deposition driven by violent storms. Hurricanes are especially effective because they combine extreme winds and extreme precipitation. As far as sediment is concerned, extreme precipitation is the greater concern because it rapidly erodes the watershed. Increased flashiness in runoff due to both land development and, more recently, attributable to climate change washes more sediment off the land surface and erodes stream beds. Storm-driven water flow can be devastatingly effective in moving large quantities of sediment in a short interval. As Hurricane Agnes passed through the Chesapeake watershed in 1972, dropping 3 to 6 inches of rain onto already saturated soils, some 31 million metric tons of sediment were swept into the Bay, depositing 40 years worth of sediments based on the average deposition rate.

The scale and geometry of Chesapeake Bay make it particularly vulnerable to tropical cyclones that travel a path with their center or eye moving on the west side of the Bay.113 While eastern-track storms act to force water out of the Bay, these western storm tracks create destructive storm surges, such as occurred during the recent 2003 Hurricane Isabel. The linear nature of the Bay and its larger tributaries enables long fetches that allow efficient transfer of wind forces that drive these larger surges; these surges enhance the natural two-day oscillation of water level in the Bay.

As discussed in Section 7, global climate is very likely to accelerate sea-level rise and thus the erosion and inundation wetlands and low-lying lands. Erosion, as the shoreline retreats inland, will disperse sediment into the Chesapeake Bay and Coastal Bays, further contributing to the excess turbidity that limits light penetration. Stronger hurricanes and non-tropical storms, which are likely in this warming era, will increase the probably of sustained heavy downpours such as experienced during Hurricane Agnes. Such large storms that are accompanied by heavy and widespread precipitation throughout the watershed can have pervasive and lasting impacts on coastal ecosystems. Hurricane

![Hurricane Agnes rainfall accumulations.](image)

![Shoreline erosion from storms.](image)
Agnes not only added a huge quantity of sediments to the Chesapeake Bay, but also added nutrients and organic matter, devastated oyster reefs and aquatic vegetation beds, and affected key species, with repercussions to the ecosystem lasting for decades.

**LIVING RESOURCES**

**Present mixture of cool and warm species**

The Chesapeake Bay is famous for its role in supporting spawning, nursery, and feeding habitats for diverse and important living resources. Historically, U.S. fisheries for shad, herrings, striped bass, menhaden, and oysters were centered here in the Chesapeake Bay. The Chesapeake Bay remains one of the most important nurseries for striped bass, croaker, eels, and blue crabs. The Atlantic menhaden fishery is now principally limited to the lower Chesapeake Bay, reflecting the productive feeding conditions that occur there during summer and fall months. Size, surrounding geography, tides, currents, and other physical features all contribute to the Chesapeake Bay’s productive food webs. But the diversity and year-to-year abundances of living resources also depend heavily on the Chesapeake Bay’s latitude and seasons. The Chesapeake Bay represents a transition zone between more southerly ranging temperate-subtropical species and more northern range boreal-temperate species. Interestingly, the Chesapeake Bay also shows the greatest seasonal temperature range of any other major U.S. Atlantic estuary. Therefore, in the future, warming in the Chesapeake will likely diminish the role of boreal-temperate species (Figure 8.3) and affect seasonal temperature fluctuations, which currently have an important role in nursery function and how food webs and fish communities are structured.114

**Shift to warm species**

More northerly, cool temperature species such as eelgrass, soft shell clams, and sturgeons have already been in decline in the Chesapeake Bay. Soft shell clams occur at their southern limit in the Chesapeake Bay and their Maryland landings have declined from over 6 million pounds in the 1960s to less than 300,000 pounds in recent years.115 Trends of diminished production of soft shell clams in Europe are related to climate, with poor juvenile production linked to warming at the southern extreme of its range in the Netherlands portion of the Wadden Sea.116 Warming in the Chesapeake and Coastal Bays, coupled with existing stresses due to disease, pollution, and sediments, is likely to eliminate commercial harvests of the once economically important soft shell clam in the coming decades and may extinguish its local populations altogether. As indicated below, warming will also confound efforts to restore eelgrass and sturgeons, compounding the other stresses, such as turbid waters and hypoxia, presently limiting their recovery.

Atlantic croaker is a subtropical fish that is already making significant inroads in temperate estuaries like the Chesapeake and Delaware Bay. Croaker juveniles can reside during winter months in Mid-Atlantic estuaries but can occasionally experience lethally cold temperatures, particularly to the north. During recent decades, more moderate winter temperatures in the Chesapeake Bay have increased juvenile growth and survival. Indeed during the last twenty years, Chesapeake landings are expanding their range in the Mid-Atlantic.
of Atlantic croaker have increased ten-fold to 8.6 million pounds in 2006 and now exceed commercial landings for striped bass (3.6 million pounds).\textsuperscript{117}

The Atlantic croaker belongs to the drum family, which also include black drum, red drum, weakfish, spotted and speckled sea trout, spot, and Northern and Southern kingfish. Other members of this family of fishes, together with other more subtropical species, are likely to become more frequent and longer term visitors to the Chesapeake Bay. Fish species that already occur in Virginia coastal waters that should also become more prevalent and abundant with increased coastal water temperature include southern flounder, cobia, spadefish, Spanish mackerel, mullet, tarpon, and pinfish. On the other hand, more temperate species such as yellow perch, white perch, striped bass, black sea bass, tautog, summer and winter flounders, silver hake, and scup will be stressed by warming of the coastal waters.

Milder winters could also allow brown and pink shrimp to complete their life cycles in the Chesapeake and Coastal Bays, where they are now only occasional summertime visitors. These shrimp are abundant in North Carolina (e.g., Pamlico Sound), where they support important fisheries. Establishment of shrimp populations in the Chesapeake Bay could result in important commercial opportunities in the future, but would also have important but unpredictable effects on both the prey and predators of shrimp.

Warmer winter temperatures could also favor the establishment of invasive populations of nonnative species. This is particularly true for species from distant parts that hitchhiked on or in the ballast water of ships. Also, species may escape captivity and establish local populations. For example, the beautiful lionfish, a native of the Indo-Pacific and popular with salt-water aquarists, was inadvertently introduced in Florida in the early 1990s and has expanded its range northward to North Carolina, achieving populations equal in number to those of native groupers.\textsuperscript{118} Adding an additional species, such as the lionfish, to the mix has the potential to adversely affect native fishes through competition for prey and habitat and by directly eating native juveniles. With warming of coastal ocean temperatures, the lionfish is expected to continue a northward range expansion (Figure 8.4). Similarly, warmer waters may aid the spread (accidental or otherwise) of northern snakehead fish, which now occurs in the Potomac River\textsuperscript{119}, to other parts of the Chesapeake watershed.

\textbf{Changed seasonality}

Several important fish species show cycles of dominance that are the opposite of each other. Bluefish were abundant in the 1970s and 1980s but then declined during the recent period of high striped bass abundance. These cycles are thought to be due to the seasonal patterns of temperature and precipitation. Winter and early spring conditions seem particularly important in ‘setting the clock’ for patterns of juvenile production observed during the subsequent summer and fall seasons. Cold winter temperatures and high winter flows are associated with high abundance later in the year of juvenile Atlantic silversides (an important forage fish), striped bass, white perch, and Atlantic needlefish.\textsuperscript{120} Species associated with the converse—low winter flows and high winter temperatures—include bluefish, spot, bay anchovy, and northern puffer.
Shifts between these two groups occur even when winter temperatures differ less than 2°F, well within the range of warming projected in the next fifty years. Species will adapt to some degree to changing environmental changes, but because this will require generational time scales, lowered abundance of the group of species that includes striped bass are likely for the Chesapeake Bay.

Milder winters would lead to longer growing seasons for species such as sea grasses, oysters, blue crab, eels, white perch, and the resident portion of the striped bass population. Blue crabs become functionally dormant during winter months when temperatures drop below 50°F. Below 41°F in bottom waters, winter temperatures become lethal. Winter temperature projections indicate a 20% reduction in the number of days with less than 50°F by 2050 and, under the higher emissions scenario, a 36% reduction by 2100. The projections suggest that by mid-century there would be no severe winters with more than a week of water temperatures below 41°F. These warmer conditions are likely to shorten the time it takes for blue crabs to grow and reproduce, leading to increased productivity and yield to commercial fisheries. Of course, this assumes that there would be sufficient prey for blue crabs and that warming during the summer does not reduce the growth rate or increase the death rate as a result of greater disease incidence or expanded hypoxia.

The degree to which the Chesapeake Bay freezes over is already much reduced in comparison to fifty years ago. The reduced occurrence of ice in shoreline habitats could permit oysters to colonize sheltered shorelines and very shallow waters to form reefs that emerge at low tide, much as they do now in North Carolina. Such reefs could provide new opportunities for restoration and aquaculture by enabling access and enforcement of protection of rebuilding or leased bottom reefs.

Warming and the shifting of seasons are likely to affect migration and spawning behaviors of Chesapeake Bay fish. Striped bass, shads and other fish that migrate into the Chesapeake for spring spawning will likely shift their arrival times to earlier dates. Such a shift is already apparent in migrating fish in other regions. Spawning migrations by Atlantic salmon in the Connecticut River are now over ten days earlier than in 1978. American shad migrated five weeks earlier in 1993 than in 1949 in the Columbia River. Changes in timing of spawning migrations by adult fish can influence early survival and growth of their offspring. For instance, fish larvae in the Chesapeake Bay rely on spring plankton blooms to support their growth and development. Early spawning migrations by adults could result in a ‘mismatch’ between spawning and plankton blooms needed to support the growth and survival of larvae (Figure 8.5).

Another type of mismatch that can occur is between migration timing and fishing regulations. If changes in the timing of migration are sufficiently large, they may impact the timing and duration of a fishing season. For example, the Maryland ‘trophy’ striped bass recreational season targets post-spawning individuals. Here, early spawning could effectively reduce the fishing season if the season has a fixed start date. In response to increasing temperatures, management agencies may need to explore temperature-specific regulations, rather than fixed fishing seasons.

The Great Shellfish Bay
Native Americans referred to it as Chesepiooc, or...
great shellfish bay, because of the vast abundance of oysters that once characterized the Chesapeake Bay. Decimated initially by overharvesting that resulted in removal of their reefs themselves and later by introduced diseases, native oysters are present at a very small fraction of their original abundance. Substantial efforts are underway to try to determine how to increase oyster aquaculture and to restore oyster reefs for the role they play in providing habitat for other organisms and clearing up estuarine waters by their filter feeding.

Variations in climate have always been important in determining the success of oysters. Temperature and precipitation—through its effect on salinity—affect reproduction, the development of larvae, and the survival of newly settled oyster spat. Still, through the 1970s, the abundance of juvenile oysters in one year was heavily influenced by the abundance of the adult parents the year before. Recently, it appears that at such low abundance, the number of adults has relatively little influence on the number of juveniles, which is now predominantly determined by water temperature and particularly salinity. If higher river runoff regularly lowers Bay salinity, fewer juvenile oysters would be expected to survive, but if sea-level rise increases the volume of the Bay sufficiently to increase salinity, the reverse would be true.

The two prevalent oyster diseases, commonly called Dermo and MSX, are also likely to respond to climate change. Dermo epidemics are more severe in Chesapeake Bay after dry and warm winters. Increased water temperatures cause more rapid cell growth by the Dermo parasite once it has infected an oyster. As conditions have warmed, Dermo has extended farther up the East Coast, even to New England. But it may be the case that the Chesapeake Bay is already warm enough so that temperature is not a factor limiting Dermo epidemics except under higher salinity conditions. MSX is also more prevalent in oysters after dry and warm winters and less so following cold winters (less than 37°F) and under low salinity.

Successive cold winters keeps MSX in check, but, as this becomes less likely with the warming waters of the Chesapeake Bay and Coastal Bays, this disease is likely to remain at least as prevalent if not more so.

Overall, the net effects of climate change on oyster populations, aquaculture, and restoration are difficult to project. They will depend not only on the direct effects of salinity and temperature on oyster growth and survival, but importantly on how the changing conditions affect the prevalence and virulence of the disease organisms, which warmer conditions should favor. Still, it should be remembered that native oyster populations prosper in Gulf Coast estuaries, which experience higher temperatures and more variable salinities.

**Aquatic vegetation**

Submerged aquatic vegetation (vascular plants that live underwater) constitutes a very important component of the Chesapeake Bay and Coastal Bay ecosystems. These plants increase water quality in shallow water areas by reducing the resuspension of sediment and releasing oxygen to the sediments, thereby enhancing nutrient recycling. The vegetation provides habitat for many animals, including blue crabs, which use it as a refuge from predators during early life. There is currently a worldwide decline in coastal submerged plants, or seagrasses, including in the Chesapeake Bay and Coastal Bays. Much

**Warmer conditions have allowed oyster diseases to spread**

---

Oyster reef, Chesapeake Bay.

Aquatic vegetation provides habitat for juvenile fish and crabs.
of this loss is a result of nutrient over-enrichment, which increases shading by phytoplankton and stimulates the growth of algae on the blades of vegetation, thereby reducing the light needed for photosynthesis.\textsuperscript{93}

Aquatic vegetation requires suitable temperature, salinity, nutrients, and, in particular, light.\textsuperscript{132} Climate change could affect, directly or indirectly, all of these variables. As in the case of fish and other animal species, aquatic plant species have different latitudinal distributions that are closely related to their temperature tolerance. The dominant aquatic plant species under the higher salinity conditions of the lower Chesapeake Bay and the Coastal Bays is eelgrass (\textit{Zostera marina}), a boreal-temperate species with a southern limit of distribution in North Carolina.\textsuperscript{133} Largely as a result of declining water quality and increased light limitation, eelgrass has become much less abundant in Maryland bays. During the high salinity and high water clarity conditions that existed in the 1960s, eelgrass was found as far up the Chesapeake Bay as Kent Island, but now is largely limited to the Tangier Sound region (Figure 8.6), where it provides valuable habitat for early juvenile blue crabs and refuge for the highly vulnerable soft stages of adults.

At high summer temperatures, eelgrass photosynthesis cannot keep pace with its respiration and the plant loses its leaves and even its belowground rhizomes may die.\textsuperscript{134} During unusually hot summers, for example in 2005, the dieback of eelgrass was extensive and recovery in the following year was dependent on the bank of seeds left in the sediment. Because eelgrass seeds do not remain viable for over a year, if there were a succession of hot summers, eelgrass populations could be eliminated from the Bay. Consequently, the outlook for eelgrass in the warming bays is not promising. By mid-century, it is as likely as not that eelgrass beds will no longer exist in the Chesapeake Bay under the lower emissions scenario, and likely that it will be functionally eliminated under the higher emissions scenario. It is very likely that eelgrass will be completely extirpated by the end of the century under either scenario. It is possible, however, that shoalgrass (\textit{Halodule beaudettei}), a subtropical species that is abundant in higher salinity portions of North Carolina’s sounds could colonize the Chesapeake Bay and Coastal Bays as the winters warm. However, it does not tolerate low salinity as much as eelgrass and, thus, its distribution in the upper Bay would be more limited. Shoalgrass is also more ephemeral and provides less robust habitat than eelgrass.

As sea level continues to rise, increasing water depths will reduce the light available to aquatic vegetation where it presently occurs. However, the vegetation could migrate shoreward and even occupy areas that are presently tidal wetlands or dry land. However, as wetlands erode away, hard clay-rich deposits often remain, a consolidated remnant of older wetland soils. These clay deposits are not suitable soils for submerged vegetation and until covered by a veneer of sand will not be colonized.\textsuperscript{135} With the increased volume of the Chesapeake Bay because of accelerated sea-level rise, higher salinity conditions are likely to extend farther up the Bay. While greater intrusion of salinity may be beneficial to seagrasses such as eelgrass and shoalgrass (if it successfully colonizes the Bay), it could constrict the habitat suitable for plants originating from fresh waters, such as redhead grass and sago pondweed, that are prevalent in lower salinity regions, where aquatic vegetation is currently expanding as water quality improves.\textsuperscript{93}

While the net effects of climate change on aquatic vegetation are difficult to predict because of the complex and interacting effects of temperature, salinity, water quality, and sea level, it is very
likely that the biomass, species composition, and distribution of aquatic vegetation in the Chesapeake Bay and Coastal Bays will be significantly affected by climate change.

**OCEAN ACIDIFICATION**

In addition to its greenhouse effect, the increase in the concentration of carbon dioxide in the atmosphere is gradually acidifying, or lowering the pH, of the ocean. Much of the carbon dioxide that is released from human activities is actually taken up by the ocean, moderating its effect on global warming. However, when carbon dioxide dissolves in sea water, it decreases its pH. From the beginning of the industrial era, pH has declined about 0.1 units from its normal 8.18, and may decline by a further 0.3 to 0.5 units by 2100. While this will not make the oceans actually acidic (below 7 pH units), such a decline in pH affects the ability of organisms to create shells or skeletons of calcium carbonate because lowering the pH decreases the concentration of the carbonate ions that are required.

Ocean acidification is the sleeper issue of global change, because not only are the potential effects on the world’s coral reefs profound, but the process of acidification also reduces the ocean’s capacity to absorb more carbon dioxide from the atmosphere. The effects of ocean acidification have just recently been receiving attention, most of which is focused on corals and the plankton of the open ocean. Recent studies have shown that mollusks that are ecologically and economically important in coastal waters may be vulnerable to the effects of ocean acidification. Mussel and oyster calcification rates were projected to decline by 25% and 20%, respectively, by the end of the century, as well as the ability of oyster larvae to form their thin shells when pH was reduced to 7.4 through addition of carbon dioxide.

Research on the processes and effects of acidification in Mid-Atlantic estuaries and coastal waters has scarcely begun. Important questions remain regarding the interaction of the bicarbonate created when carbon dioxide dissolves in these waters with other chemical constituents. This will affect the level of acidity likely to be experienced and the effects that might be realized not only on mollusks, but also crustaceans, starfish, and other organisms that create calcareous skeletons.
Section 9

HUMAN HEALTH

KEY POINTS

> Health risks due to heat stress are very likely to increase if emissions are not reduced.
> Under the higher emissions scenario, in particular, heat waves are projected to greatly increase risks of illness and death before the end of the century, with an average of 24 days per summer exceeding 100°F. Some, but not all, of these increased risks can be reduced by air conditioning and other adaptation measures.

> Respiratory illnesses are likely to increase, unless air pollution is greatly reduced.
> More ozone, responsible for multiple respiratory illnesses, is formed under prolonged, high temperatures. Releases of air pollutants (nitrogen oxides and volatile organic compounds) that cause ozone to be formed have been declining, but would have to be reduced much more to avoid a reversal in progress toward achieving air quality standards.

> Increased risks of pathogenic diseases are less likely.
> The mortality due to vector-borne and non-vector borne diseases in the United States is low because of public health precautions and treatment. Climate change might affect the exposure of Marylanders to pathogens such as the West Nile virus, but precautions and treatment could manage this risk.

Human well-being is obviously affected by the weather and the changing climate will have multiple ramifications for human health as well as comfort and enjoyment. Human health has the greatest sensitivity to climate change with regard to heat stress; the effects of storms that generate floods and extremely high winds; air pollution effects, particularly as they cause or exacerbate asthma and other respiratory maladies; and diseases caused by pathogens that are borne by insects and other vectors, water, and food. The risk of storms and floods are addressed earlier in this assessment. Here the potential impacts of climate change-related heat waves, air quality, and pathogenic diseases on human health in Maryland are evaluated.

HEAT WAVES

Global warming is likely to result in substantially higher temperatures both in winter and summer in Maryland. While there could be some benefits in terms of reduced deaths from cardiovascular disease (for example, as result of milder winters) Maryland’s population experiences very few deaths with its temperate climate related to extreme winter temperatures. Rather, most assessments in the United States have appropriately focused on the health risks of extreme heat. In six out of ten recent years, heat has been the leading weather-related killer in the United States. Concerns about the increased health risks from heat waves caused by global warming are not far-fetched. The death of an estimated 35,000 people, attributable to the August 2003 heat wave in Europe, was a sobering experience. Parts of France experienced seven consecutive days with temperatures more than 104°F and 14,800 people died in that country alone. The situation in Europe

Dawn brings on the day’s heat.
was particularly acute because the population was not acclimated to warm summers and there was little air conditioning. Most of those who died were elderly. Closer to home, a 1995 heat wave in Chicago resulted in an estimated 696 deaths. While the European heat wave was related to unusual weather patterns and not primarily to climate change, climate models predict frequent summer conditions not unlike those in 2003 during the latter part of the 21st century, indicating that, for many purposes, the 2003 event can be used as an analog of future summers in climate impact assessments.

Heat stress can result in illnesses caused by heat cramps, fainting, heat exhaustion, and heatstroke and result in death. Except for cramps, heat-related illnesses are the result of the body’s failure to regulate its internal temperature. Our bodies respond to hot weather by an increase in blood circulation and increase in perspiration, both in an attempt to rid the body of heat. The effectiveness of such heat loss is reduced when air temperature and humidity increase. The ability to increase circulation may be limited by heart rate and the blood volume, which is reduced because of the loss of body fluids.

Several factors can increase the risk of heat-related illness. Both individuals over 65 and the very young are at higher risk because they have less ability to control internal temperatures and are more susceptible to dehydration. Reduced physical fitness, obesity, existing illnesses, and the use of medicinal drugs such as stimulants and beta-blockers all increase the risk of heat stress. Individuals not acclimated to high temperature or suffering from exertion are also more susceptible. City dwellers, particularly those of lower economic status who cannot afford air conditioning, are at greater risk because of the urban heat island effect, where buildings and paved surfaces hold the heat well into the night. Many of those who die of heat stress live alone and do not seek treatment or are not discovered until it is too late. And most of those who die in urban areas as a result of heat stress succumb during the night, when temperatures are expected to rise even more than during the daytime.

The average annual frequency of days with a maximum temperature exceeding 90°F in Maryland is projected to grow gradually over the century, but more dramatically later in the century. Near the end of the century under the lower emissions scenario, the model averages project about 64 days per year would exceed 90°F and 10 days per year would exceed 100°F (Figure 4.4). Under the higher emissions scenario, these numbers would grow to 95 and 24 days per year, respectively. These numbers would be higher in urban areas due to the urban ‘heat island’ effect. These projections are generally similar to those derived by the Northeastern Climate Impacts Assessment for Philadelphia (Figure 9.1). Put another way, these projections indicate that toward the end of the century under the high emissions scenario, it would be a rare summer day when the high temperature did not top 90°F and there would be nearly a month where temperatures reached 100°F. A considerable increase in 90°F days is very likely inevitable, even if greenhouse gas emissions were reduced around the middle of the century.
emissions scenario), but only about half as many 100°F days would occur if emissions were reduced.

Of course, as the frequency of very hot days increases so does the likelihood that there will be a successive number of these days, i.e., a heat wave. Based on the model projections, there is a high probability that, late in the century, heat waves with daily temperatures exceeding 90°F would last more than 60 days is high under the higher emissions scenario. Under the low emissions scenario in most years, heat waves would not exceed 20 days. The difference between the scenarios is even greater for severe heat waves such as experienced in Europe in 2003 (successive days with temperature exceeding 100°F).

Based on these temperature and heat wave projections, Maryland is likely to confront substantially increased heat-related health risks by the mid-century and beyond. By late in the century under the high emissions scenario, this situation is likely to become very serious, with life threatening conditions developing nearly every year, particularly in the Baltimore and Washington urban areas because of the urban heat island effect and more at-risk individuals living there. Beyond threatening life for the most vulnerable, these oppressive conditions would curtail outdoor activities and diminish productivity in commercial activities requiring outdoor work. Under the lower emissions scenario, heat-related health risks would increase substantially from the present condition but much less so than with the unmitigated growth in emissions.

Of course, there are steps that can be taken to lower these health risks. Within limits, acclimation to higher outdoor temperatures and various adaptation measures can lower the incidences of heat-related deaths. Adaptation measures include effective early warning and response plans for heat waves, air conditioning, and better education about personal precautions, such as drinking more fluids, wearing light colored and loose fitting clothing, and limiting outdoor activity. Over the longer term, building codes can be designed to reduce the urban heat island effect, for example, by increasing the tree canopy and including reflective or green roofs. More frequent and severe heat waves will very likely increase requirements for air conditioning, extend the air-conditioning season, and increasing peak-load electricity demands at the very time there will be a premium on energy conservation to mitigate greenhouse gas emissions.

**AIR QUALITY**

Global climate change could affect human respiratory health by changing levels of air pollutants and the types and levels of pollen. For the United States, impacts of climate change on ground level, or tropospheric, ozone are much more likely to be more important than for other air pollutants. This is due to the importance of high temperature in the formation of ozone as well as the large areas of the country currently affected by ozone levels exceeding national standards (Figure 9.2). Central Maryland is among the most affected regions in the nation.

Ozone can affect human health by irritation of the respiratory system, reducing lung function, aggravation of asthma by increasing sensitivity to allergens, increased susceptibility to respiratory infections, and inflammation and damage to the lining of the lungs, causing chronic obstructive pulmonary disease (COPD). Effects can range from coughing and shortness of breath to permanent
scarring of the lungs and even death. Central Maryland has some of the highest incidence of asthma and acute respiratory illness in the country. It is estimated that about 2,000 Marylanders die each year because of chronic lower respiratory illnesses.

Maryland has made substantial progress in controlling air pollution. Baltimore and Washington areas are on a path leading to compliance with the National Ambient Air quality Standards (NAAQS) by 2009, but changes in the global background could reverse this progress and require even deeper reductions of the pollutants responsible for ozone formation. Human activities do not emit ozone per se, but our activities result in the release to the atmosphere nitrogen oxides (NOx), carbon monoxide (CO), and volatile organic compounds (VOCs). NOx and CO are emitted mainly by the combustion of fossil fuels and VOCs are emitted from incomplete combustions of fuels and the evaporation of petroleum fuels and chemicals and by certain plants. These compounds react with oxygen in the atmosphere in the presence of sunlight to create ozone (O3; Figure 9.3).

The process of ozone formation depends on high air temperatures, which explains why we do not have ozone alerts during the winter even though emissions of NOx and VOCs are just as high then. As Figure 9.4 shows, there is a clear relationship between the maximum temperature at the Baltimore-Washington International Airport (BWI) and ozone concentrations in the Baltimore non-attainment area. Furthermore, heat waves (multiple successive days with very high temperatures) create the optimum conditions for ozone formation. This is apparent in the Baltimore non-attainment area where the number of days where ozone concentrations exceed the 8-hour “Code Orange” standards in a year shows close relationship with the number of days where maximum temperatures exceed 90°F (Figure 9.5).

Climate change is also likely to decrease the occurrence of cyclonic waves (low pressure system with associated weather fronts), thus lengthening
the duration of stagnant, high pressure events (hot and hazy periods) and delay the onset of cold fronts that clean up air pollution episodes. Such smog episodes not only decrease the visual range but can also cause human illness and death due to higher concentrations of fine particulate matter. The persistent Bermuda High leads to weak or stagnant winds, high daytime temperatures, and intense UV radiation reaching the Earth's surface. Pollution and VOCs build up from gasoline vapors and even trees, particularly pines and oaks that are favored by global warming. All of this is exacerbated by the urban heat island effect.

Based on the increase in summer temperatures and heat waves and these changes in weather patterns, scientists have projected anything from a 3-5 ppb increase of NOx and VOCs to a 10-20 ppb increase in 8-hour average ozone concentrations over the eastern United States by the end of the century, assuming emissions of the ozone-precursor pollutants remain constant. One recent study projected a 28% increase in the average number of days exceeding 8-hour ozone standards for Baltimore and a 50% increase for Washington, D.C. by 2050. On the other hand, if emissions of NOx are reduced by 50%, then ozone concentrations could, according to another study, actually decline by 11-28% despite the warming conditions. The decline in observed ozone concentrations in the Baltimore region for given temperature ranges (Figure 9.6) provides clear evidence of the importance of reducing precursor emissions.

In summary, it is very likely that without significant additional reductions in air pollution by NOx and VOCs, ground level ozone concentrations will increase and pose additional health risks to people residing in central Maryland. In addition to mitigation by reducing pollutant emissions, adaptive responses are similar to those for heat stress: warning systems, air conditioning, avoiding exertion and outdoor activity, and increasing tree cover.
PATHOGENIC DISEASES

Climate change can increase human exposure and vulnerability of diseases caused by pathogenic microorganisms. These include diseases borne by various animal vectors, such as malaria, dengue, Lyme disease, and encephalitis, a type of which may be caused by the West Nile virus. Global warming could increase the range or abundance of the animal vectors. Climate change could also affect exposure to non-vector borne diseases such as hantavirus, cryptosporidiosis, and cholera. The incidence and associated mortality of most of these diseases in the United States is relatively low because of public health precautions and the availability of treatment. For Maryland, the increased risks due to heat stress and respiratory impairment are likely to be more serious than for pathogenic diseases.

Moreover, it is difficult to project how climate changes would impact pathogenic transmission and human health because of the complexity of climatic effects on vectors and other environmental factors. Cryptosporidiosis is an intestinal disease caused by a bacterium that is abundant in livestock feces and can be transported during high rainfall events. The bacterium is small and resistant to chlorination, making it difficult to kill or filter out of water supplies. Lyme disease has become the most important vector-borne diseases in the United States and a large majority of cases occurs in the Northeast, although it is less prevalent in Maryland than in the states to the north. The ticks that transmit Lyme disease prefer cooler temperatures during the summer, so the projected warming could reduce tick populations and disease risk. Continued encroachment of suburbs into former woodlands presents a far greater risk for contraction of Lyme disease. Outbreaks of West Nile virus in humans seem to occur when extreme heat and drought are followed by heavy rains. It is thought that birds that host the virus migrate to wetter areas during the drought and the mosquitoes that normally prey on birds switch to humans when they hatch following the rains.

The dark pink area, which includes most of Maryland, represents a medium density of host-seeking ticks that have been shown to be infected with Lyme disease bacteria.
KEY POINTS

- Reduction of greenhouse gas emissions has substantial benefits for Maryland. Mitigation of global emissions by mid-century would very likely result in significantly lower sea-level rise, reduced public health risks, fewer extreme weather events, less decline in agricultural and forest productivity, and loss of biodiversity and species important to the Chesapeake Bay. Even more serious impacts beyond this century would be avoided.

- Develop adaptation strategies for human health, water resources, and restoration of bays. Adaptation strategies to reduce coastal vulnerability should plan for a 2 to 4 foot rise in sea level during the century. The Commission should evaluate additional adaptation strategies related to human health, water resources, forest management, and restoration of the Chesapeake Bay and Maryland’s Coastal Bays.

- Organize and enhance Maryland’s capacity for monitoring and assessment of climate impacts. A more extensive, sustained, and coordinated system for monitoring the changing climate and its impacts is required. Maryland is in a strong position to become a national and international leader in regional-to-global climate change analysis and its application to mitigation and adaptation.

This assessment of the impacts of climate change on Maryland was undertaken as one of three integrated components of the Plan of Action of Maryland’s Commission on Climate Change. To that end, it is appropriate to draw implications from the impacts assessment to inform the other efforts to mitigate climate change by reducing greenhouse gas emissions and to adapt to changes likely, thereby reducing Maryland’s vulnerability. This concluding section briefly summarizes the findings of the impacts assessment related to those two objectives.

MITIGATION

Reducing emissions soon is required

The Intergovernmental Panel on Climate Change has demonstrated that on a global scale, there are likely to be large changes in climate and substantial and serious effects on natural ecosystems, resources, and human populations and societies.3 The IPCC showed that some of these changes are inevitable because they have already begun and cannot easily be stopped, even with dramatic and immediate reductions in greenhouse gas emissions. However, the path that humankind will follow in either continuing to increase those emissions or reducing them will have a large effect on the extent of climate change and magnitude of its consequences.

This assessment seeks to identify both those changes in Maryland that are likely inevitable and those changes that can be avoided with action to reduce emissions through the use of the lower and higher emissions scenarios. A point made earlier bears repeating: the higher emissions scenario is not...
and does not represent a ceiling nor the most extreme changes that are likely, and the lower emissions scenario is not a floor and does not represent the minimum effects that may be achievable. Currently, emissions are growing faster than the higher scenario assumes. The IPCC estimated that it would require early reductions of global greenhouse gas emissions of 50 to 85% by 2050 to constrain the increase in the global mean temperature to 3.6 to 4.5°F, a level of warming generally thought to have dangerous consequences, and would, therefore, still have many negative consequences as this report attests. Under the lower emissions scenario used in this assessment, the emissions in 2050 would be declining but still be about 30% higher than today. For that reason, the IPCC is planning to develop scenarios incorporating earlier and more dramatic emission reductions in its future assessments.

For the most part, the projections of impacts under the lower and higher emissions scenarios are similar or only modestly different at the middle of the 21st century. This is hardly surprising because the cumulative emissions are little different between the two scenarios by that point in time (Figure 3-3). The differences become starker towards the end of the century, even though the lower emissions scenario shows only about a 50% reduction in emissions by that time. Thus, the lower emissions scenario projections represent what might be considered the maximum change that could be expected if the mitigation strategies now being advanced in international negotiations are implemented. With that in mind, the following are some of the more severe impacts projected for late 21st century climate change in Maryland that could potentially be avoided by global action to reduce greenhouse gas emissions during the first half of century:

- More extreme rainfall events, but also longer lasting summer droughts, not unlike the unusual conditions seen in Maryland over the past year.
- Declines in agricultural productivity, which may be initially enhanced due to warmer temperatures and higher carbon dioxide concentrations, as a result of severe heat stress and the summer droughts.
- Reduced forest productivity and ability to sequester carbon, after a modest increase during the first half of the century, as a result of heat stress, seasonal droughts, and outbreaks of pests and diseases; the loss of maple-beech-birch forests of Western Maryland and an increase in pine trees in the landscape of the rest of the state; and the withdrawal of northern bird species such as the Baltimore oriole from Maryland.
- The permanent loss of important species such as eelgrass and soft shell clams from the Chesapeake Bay; highly stressful summer conditions for striped bass and other fish as the dead zone expands and surface waters heat up; and a substantially more difficult challenge in restoring the health of the Bay by reducing nutrient pollution.

Limiting the projected impacts in this assessment to the 21st century undervalues the full benefits of mitigation of greenhouse gas emissions taken early in the century. The impacts of unmitigated climate change will not stabilize in 2100 but continue beyond, in some cases at an accelerated pace. In fact, some responses have a long lag effect, meaning that the effects will continue to grow over centuries. This is particularly true for sea-level rise.
This image shows the calving front, or break-off point into the ocean, of Helheim Glacier, located in southeast Greenland. The image, taken in May 2005, shows high calving activity associated with faster glacial flow. This glacier is now one of the fastest moving glaciers in the world.

Impacts of climate change will not stabilize in 2100, and sea level will continue to rise

because of the slow process of warming the ocean and the continued melting of polar ice sheets. If emissions continue to grow at the pace of the higher emissions scenario or greater, it is likely that the climate system will be committed to an accelerated melt down of the polar ice sheets over the next few centuries that could not be stopped by reducing greenhouse gas emissions.

Lest one think that is such a long time in the future, remember that European colonization of Maryland began 374 years ago and Maryland became a state 227 years ago.

Changing conditions affect mitigation

Conditions will change in ways that affect mitigation options. For example, forests that are stressed by heat and low soil moisture during the summer will cease to take up and hold (or sequester) carbon from the atmosphere. Instead, they will tend to release stored carbon back into the atmosphere as carbon dioxide. Heat stress will increase the demand for air conditioning and extend the cooling season. At times, air conditioning will not be a luxury, but a matter of survival. This would offset mitigation savings through energy conservation and increase peak electricity demand, which determines the generation capacity required.

Some of the projected climate changes are likely to make the accomplishment of present environmental objectives more difficult, for example, attaining ozone concentration standards by reducing air pollution or achieving the Chesapeake Bay restoration goals by reducing nutrient agricultural and urban runoff of nutrients and sediments. However, most of the projected impacts of climate change will not be realized until the middle of the century or later, and some are not yet very predictable. Therefore, there is ample opportunity to continue to pursue those environmental objectives aggressively because this would lessen the impacts of climate change later on. Freezing action due to the uncertain effects of climate change would result in unavoidable and more severe consequences.

ADAPTATION

Sea-level rise and coastal vulnerability

Based on the current scientific understanding of the complex processes that will affect future sea level as considered in the projections of this assessment, it is prudent to plan now for one foot of relative sea level rise by the middle of the century and at least two feet by the end of the century. For major, long lifetime investments in property and infrastructure, it would be prudent to consider an additional margin of safety by planning for a four foot rise in sea level. New observations of the global and local rates of sea level rise, new scientific understanding of the processes of melting of polar ice sheets, and improved capabilities for long-range storm forecasting could alter this advice, but more severe impacts are not likely to be realized until the second half of the century. Consequently, plans and policies should be periodically reevaluated with regard to this emerging understanding and the progress in reducing greenhouse gas emissions.

Subsequent adaptation strategies

The Maryland Commission on Climate Change will...
continue to evaluate adaptation strategies in addition to sea-level rise and coastal vulnerability over the next year or more. Although detailed evaluation of adaptation options is beyond the scope of this report, the assessments provided here should serve as a useful basis for evaluation of adaptation strategies appropriate for Maryland in the areas of human health (heat and respiratory stress), water resources (particularly emphasizing the Potomac Basin, groundwater resources, and reducing the effects of urbanization on flooding and stream health), forest management (changing sequestration potential and managing forest succession, diseases and pests), and restoration of the Chesapeake Bay and Maryland's Coastal Bays (building on the recent analysis of the Scientific and Technical Advisory Committee of the Chesapeake Bay Program). These issues are ripe for further evaluation by the Commission.

**Monitoring, assessment, and forecasting**

In general, there is insufficient monitoring of Maryland’s climate, environmental conditions, and resources to characterize their present state and variability. Now that we realize that all of these are changing and will be changing more rapidly in the future, a better system of observations is required—one that is reliably continuous, strategically targeted, and thoroughly integrated. Reliable observations, interpreted with scientific understanding, and innovative models can dramatically reduce uncertainty about the path of climate change in Maryland and its consequences, allowing us to make better informed and wise decisions about the State’s future. It is clear that traditional approaches to adaptation will not suffice in a future that no longer resembles the past. Climate models can be downscaled to incorporate locally important phenomena, such as urban heat island and forest cover effects, and resolve important differences across our slice of the Mid-Atlantic landscape.

Maryland is in a strong position to become a national and international leader in regional-to-global climate change analysis and its application to mitigation and adaptation. There is already considerable, world-recognized expertise within our public and private universities on which to build. And, Maryland has the unmatched advantage of the location of the Goddard Space Flight Center, which leads the National Aeronautics and Space Administration’s earth science program at Greenbelt; headquarters of the National Oceanic and Atmospheric Administration’s line offices at Silver Spring; and National Weather Service’s Climate Prediction Center soon to be relocated to College Park. Marshalling and enhancing this capacity for continually improving climate impact assessment would greatly benefit not only our State of Maryland, but our planet, Earth.

Hi Maria,

Congratulations on finishing the draft of your technical report! It represents a lot of hard work.

You’ll find attached the document with recommended edits tracked in Word. I found no major issues. You’ll see that most of the edits related to using the word “projected” for future estimates that are dependent on emissions scenarios and use of the conditional voice (could, might) when talking about the future. I did not have time to add explanatory comments for each edit - I know that you’ll easily grasp the rationale behind individual edits. You can call me on my personal cell phone (b) (6) for any questions.

All the best,

Patrick

Patrick,

No problem. You don't need to hurry it. I can wait until Monday. I'm attending the Geological Society of America meeting this week, so I have other things I can do with my time. I just thought I might take a poke at some edits during my downtime between papers.

Hi Maria,

I’m sorry for the delay in reviewing your report. I travelled, then gave two presentations, then was on leave. If you can wait until tomorrow, I can make suggestions to the Word document though track changes.

Patrick
Hi Patrick,

Do you have any edits you would like to suggest for the final report? I'm starting to make changes based on Amanda's comments, but I wanted to see if you have anything to add before I start going through it.

Cheers,

Natural Resource Stewardship and Science
Fort Collins, Colorado
The National Park Service, Natural Resource Stewardship and Science office in Fort Collins, Colorado, publishes a range of reports that address natural resource topics. These reports are of interest and applicability to a broad audience in the National Park Service and others in natural resource management, including scientists, conservation and environmental constituencies, and the public.

The Natural Resource Report Series is used to disseminate comprehensive information and analysis about natural resources and related topics concerning lands managed by the National Park Service. The series supports the advancement of science, informed decision-making, and the achievement of the National Park Service mission. The series also provides a forum for presenting more lengthy results that may not be accepted by publications with page limitations.

All manuscripts in the series receive the appropriate level of peer review to ensure that the information is scientifically credible, technically accurate, appropriately written for the intended audience, and designed and published in a professional manner.

This report received formal peer review by subject-matter experts who were not directly involved in the collection, analysis, or reporting of the data, and whose background and expertise put them on par technically and scientifically with the authors of the information.

Views, statements, findings, conclusions, recommendations, and data in this report do not necessarily reflect views and policies of the National Park Service, U.S. Department of the Interior. Abstract/Executive Summary

Changing relative sea levels and potential increasing storm surges due to anthropogenic climate change present many challenges to land managers. This report summarizes work done by the University of Colorado in partnership with the National Park Service to combine, compare, and contrast different sea-level change projections from the United Nations Intergovernmental Panel on Climate Change (IPCC) and storm surge scenarios using National Oceanic and Atmospheric Administration (NOAA) storm surge models. This report covers how these models are used to project sea level change in coastal units that have recently recovered from storm damage, such as the Statue of Liberty in New York. Both the IPCC and NOAA have established their own climate change scenarios, however this research will be the first to combine these results to show how storm surge could propagate in the future using bathtub models. These scenarios result in significantly different inundation outcomes. In addition to using multiple sea level and storm surge scenarios; multiple time horizons (2030, 2050 and 2100) were studied. The National Capital Region is projected to experience the highest average rate of sea level change by 2100, although the coastline adjacent to Wright Brothers National Memorial in the Southeast Region is projected to experience the highest sea level rise by 2100. The Southeast Region is also projected to experience the highest storm surges based on historical data and NOAA storm surge models. These results have far reaching implications for adaptation and mitigation strategies for lands managed by the National Park Service.
Acknowledgments

This project was funded using funds from the NPS Servicewide Comprehensive Call (FY2013–2015) and was augmented by funds from the Natural Resource Stewardship and Science Directorate’s Geologic Resources Division and Climate Change Response Program. We would like to thank the members of the communication advisory team (Lynda Bell, Ann Gallagher, Will Elder, Janet Cakir, Stanton Enomoto, Matt Holly, Shawn Norton, Larry Perez, and Ryan Stubblebine) and science advisory team (Amanda Babson, Patrick Gonzalez, Steve Nerem, and Rob Thieler) for their time and input into this project.

We would also like to thank the Susan Teel and Caroline Rohe at Gulf Islands National Seashore for their assistance designing two waysides. Likewise, we also thank Julie Whitbeck, Aleutia Scott, Kristy Wallisch, and Stacy Meyers for helping design, review, and install a wayside at Jean Lafitte National Historical Park and Preserve. Elizabeth Rogers and Kathy Krause helped design a wayside for Fire Island National Seashore.

We would also like to thank xxx for their assistance in editing and reviewing this document.

List of Terms

The following list of terms are defined here as they will be used in this report.

Flooding: The temporary impoundment of water on the land.

Inundation: The permanent impoundment of water on what had once been dry land.

Isostatic rebound: A change in land level caused by a change in loadings on the Earth’s crust. The most common cause of isostatic rebound is the loading of continental ice during the Last Glacial Maximum in North America. The North American land surface is still moving after the melting of this continental ice in an effort to return to equilibrium with its original pre-loading state.

National Park Service unit: Property owned or managed by the National Park Service.

Relative sea level: Where the water level can be found compared to some reference point on land. This term is most frequently used in discussion of changes in relative sea level. A change in relative sea level could be caused by a change in water volume or a change in land level (or some combination of these two factors).

Sea level: The average level of the seawater surface.

Sea-level change: This term is frequently used in reference to relative sea-level change. This is the product of two main factors, 1) an increase in the volume of ocean water, and 2) a change in land level. These two factors can be broken down further into other drivers that will be discussed in greater detail in other sections. This term is sometimes mistakenly confused with the term sea-level rise.

Sea-level rise: An increase in sea level. This is the result of an increase in ocean water volume caused principally by melting continental ice and thermal expansion. This term is not to be confused with increasing relative sea level, which can also be caused by decreasing land levels.
Introduction

Global sea levels are rising. While sea levels have been gradually rising since the last glacial maximum approximately 21,000 years ago (Clark et al. 2009, Lambeck et al. 2014), the onset of anthropogenic climate change has significantly increased the rate of global sea-level rise (Grinsted et al. 2009, Church and White 2011, Slangen et al. 2016, Fasullo et al. 2016). As human activities continue to release carbon dioxide (CO$_2$) into the atmosphere, we can expect the Earth's atmosphere to still continue to warm over the next century (IPCC 2013, Mearns et al. 2013, Melillo et al. 2014). As the atmosphere warms we anticipate sea levels to also rise; however, the rate of warming depends on a number of factors that have been categorized by the Intergovernmental Panel on Climate Change (IPCC) into four different representative concentration pathways (RCPs; Meinshausen-Moss et al. 2010). These RCPs are newly defined climate change scenarios that were first introduced in the IPCC's most recent climate change report (IPCC 2013) and will form the basis of this report. The aim of this report is to discuss present combined estimates of how anthropogenic climate change will impact our coastal zone via sea-level change, due to climate change, and storm surge. As temperatures change, sea levels will rise due to a number of factors that will be discussed in greater detail; however, while sea levels are incrementally rising we can also expect periods of coastal flooding caused by coastal storms and hurricanes to exacerbate the growing problem of coastal inundation (see list of terms).

When Hurricane Sandy struck New York City in 2012 it caused an estimated $19 billion of damage to public and private infrastructure (Tollefson 2013). This single storm cannot be attributed to anthropogenic climate change but the storm surge occurred over a sea whose level has risen due to climate change. While the amount of damage from this storm might seem to be extreme, we can expect a 1/100 year storm surge to cost $2–5 billion and a 1/500 year storm surge to cost $5–11 billion (Aerts et al. 2013). Looking ahead to the future we can expect storms to become more intense (Mann and Emanuel 2006, Knutson et al. 2010, Lin et al. 2012, Ting et al. 2015). When this change in storm intensity (and therefore, storm surge) is combined with sea-level rise, we expect to see increased coastal flooding and the permanent loss of land across much of the United States coastline.

Peek et al. (2015) estimated that the cost of sea-level rise in 40 National Park Service units could be in excess of $40 billion if these units were exposed to one-meter of sea-level rise. The aim of this report is to examine 118 coastal park units to: 1) quantify precisely how much projections of sea-level rise they can expect over the next century based on the latest IPCC (2013) models, and 2) how could storm surge generated by hurricanes could also impact these parks.

Format of This Report

This report is separated into five sections: introduction, methods, results, discussion, and conclusion. Results per park will be presented alphabetically by region. The 118 park units studied for this project cover six administrative regions: the Northeast, Southeast, National Capital, Intermountain, Pacific West, and Alaska. Funding for this project did not include projected changes in lake levels, although we recognize that interior waterways and lakes, especially the Great Lakes, are also
vulnerable to climate change. Further explanation on how to access the data from this project can be found in the methods sections and accompanying appendices.

**Frequently Used Terms**

Definitions of the most basic terms used in this report can be found on page viii. However, some terms require some greater explanation for their use. We are following the advice of Flick et al. (2012) in differentiating between the terms *flooding* and *inundation*. While many choose to use these terms interchangeably, we use the term flooding to describe the temporary placement of water on land. This is usually the result of storm activity and other short-lived events, such as periodic tidal action, and will therefore be used here in reference to the effects of a storm surge on land. Inundation is used to refer to the gradual permanent submergence of land that will occur due to sea-level rise.

Furthermore, the terms sea-level rise and sea-level change are also used differently. Sea-level rise refers only to rising water levels resulting from an increase in global ocean volumes. In most parts of the United States this increase in water volume will lead to increasing relative sea levels. However, in some parts of the country relative sea level is *decreasing* due to isostatic rebound. Figure 1 shows current sea level trends based on tide gauge records for United States that span at least 30-years of data.

![Sea Level Trends (2015)]()}
Figure 1. Sea level trends for the United States based on Zervas (2009). Trends are calculated for 2015 relative to global mean sea level. Each dot represents the location of a long-term (>30 years) tide gauge station. Green dots represent stations that are experiencing the average global rate of sea level change. Yellow to red dots are experiencing greater than the global average (primarily driven by regional subsidence) and blue to purple dots are stations that are experiencing less than the global average (due to isostatic rebound or other tectonically-driven factors). Source: https://tidesandcurrents.noaa.gov/sltrends/slrmap.htm

The Southeast Region of Alaska is experiencing a decrease in relative sea level. Alaska’s crust is still rebounding following the melting of large volumes of ice that had been stored on land for centuries to millennia. Alaska is also very tectonically complex with a large number of faults that contribute to this crustal motion. Even though the volume of water in this region is increasing, the rate of sea-level rise is not enough to keep up with the rate of land-based movement resulting in a decrease in relative sea level. Whether the rate of land-based motion will continue throughout this century will be discussed in further detail in other chapters; however, this is why we use the term sea-level change as a more inclusive term that better reflects regions that will experience a decrease in relative sea level (at least in the early part of this century) as well as those that will have to deal with increasing relative sea levels.

Methods

This report reflects the work of a three-year project that began in 2013. 118 National Park Service units were selected after consultation with regional managers who identified which units they considered to be vulnerable to sea level change and/or storm surge (Appendix C). Funding for this project required the following:

1. Calculate rates of sea level change over multiple time horizons for each park unit.
2. Estimate potential exposure to storm surge using the National Oceanographic and Atmospheric Administration (NOAA) Sea, Lakes, and Overland Surge from Hurricanes (SLOSH) Model.
3. Create waysides communicating about the impact of climate change in the coastal zone for three National Park Service units.

A wayside is an exhibit designed to be installed outside for visitors to find out more information about a particular subject (https://www.nps.gov/hfc/products/waysides/). Four waysides were created for three National Park Service units: Gulf Islands National Seashore, Jean Lafitte National Historical Park and Preserve, and Fire Island National Seashore. These parks were selected after consulting with regional managers who recommended units that they felt had a need for a communication product and had communication staff who were available to work with staff at the University of Colorado in the design. The finished wayside designs are in Appendix D. Each wayside design is different because each wayside was customized to reflect the messaging and/or themes of each unit.
Sea-Level Rise Data

Sea-level rise is the product of a number of factors at work. As human activities release more CO₂ and other greenhouse gases into the atmosphere, mean global temperatures will increase (IPCC 2013, Gillett et al. 2013, Frolicher et al. 2014). Rising global temperatures cause ice located on land and in the sea to melt. While the melting of sea ice is problematic from an oceanographic perspective (primarily because it will alter water temperatures and salinity), it is the melting of ice that is currently stored on land that will have the greatest impact on global sea levels.

Melting sea ice is not a cause of sea-level rise. Water level does not change when sea ice (ice wholly contained within water and not supported by land) melts. The phase shift of water from ice to liquid water does not displace an additional volume of water.

However, the melting of ice found on land, such as Greenland and Antarctica, is a significant driver of sea level rise. As ocean waters warm the density of these waters will also change causing thermal expansion. Thermal expansion is responsible for approximately 39% of sea level rise while melting ice contributed a further 47% from 1993 to 2010 (IPCC 2013). Other factors that also need to be considered are listed in Table 1.

*Data until 2009, not 2010.

*This is not included in the total because these numbers have already been included in the Greenland ice sheet.

*This is calculated as observed global mean sea level rise – modeled glaciers – observed land water storage. See table 13.1 in IPCC (2013) for more details.

Sea level rise projections for this project follow a process-based model approach. This process-based approach generates data based on the underlying processes that are responsible for sea level rise. This is in contrast to semi-empirical models that use observations in combination with any number of other variables or theoretical considerations, which in some cases include expert elicitions (surveys or interviews with other professionals to gauge their opinion) (Rahmstorf 2010, Orlic and Pasaric 2013). The IPCC cites a number of semi-empirical projections in their most recent report (IPCC 2013), but they choose to use coupled atmosphere-ocean general circulation models (AOGCM). AOGCMs are able to simulate the processes of change rather than relying on statistical inferences
that make up the semi-empirical approach. AOGCMs are considered a process-based technique, although some variables may have been derived using semi-empirical methods (IPCC 2013).

Local sea-level rise numbers for 2050 and 2100 were taken directly from the IPCC (2013) ~ownscale AOGCM regional climate model (RCM). Many park units also require estimates for shorter time horizons that fit more closely with the expected lifetime of various projects, so sea level rise projections for 2030 were calculated using IPCC RCM data for each sea level rise driver shown in Table 2 downscaled to 2030 for each RCP. All projections results are relative to the period 1986–2005 (see Appendix C for further discussion).

*Changes in ice mass derived through direct observation and satellite data.

The standard error (σ) for each site estimate was not calculated because it was beyond the scope of this project. However, it can be calculated using the following equation and data available from the IPCC (2013 supplementary material):

\[
\sigma_{tot}^2 = (\sigma_{steric/dyn}^2 + \sigma_{smb_a}^2 + \sigma_{smb_g}^2)^2 + \sigma_{glac}^2 + \sigma_{IBE}^2 + \sigma_{GIA}^2 + \sigma_{LW}^2 + \sigma_{dyn_a}^2 + \sigma_{dyn_g}^2
\]

Where: 
steric/dyn = the global thermal expansion uncertainty plus dynamic sea surface height; 
smb_a = the Antarctic ice sheet surface mass balance uncertainty; 
smb_g = the Greenland ice sheet surface mass balance uncertainty; 
glac = glacier uncertainty; 
IBE = the inverse barometer effect uncertainty; 
LW is the land water uncertainty; 
dyn_a = Antarctica ice sheet rapid dynamics uncertainty; and, 
dyn_g = Greenland ice sheet rapid dynamics uncertainty.

Initial data were exported as GeoTIFF files that could be manipulated in ArcGIS as simple bathtub models. A weighted average by shoreline was calculated for park boundaries that overlapped more than one data cell. A standard bathtub model approach was used to show the effects of sea level rise on top of mean higher high water. Areas of inundation and flooding are denoted in the maps in the blue. Additional low-lying areas that could be potentially inundated or flooded are shown in green.
These low-lying areas do not appear to have any inlet or other pathway for water, although they should still be considered vulnerable to exposure to either groundwater seepage or potential flooding via breaching. The lack of high-resolution DEMs and time constraints prevented us from attempting a dynamic modeling approach (see limitations below). Maps were created to illustrate inundation for all park units for 2050 and 2100 under RCP 4.5 and RCP 8.5.

**Figure 2.** An example of how areas of inundation appear in ArcGIS. In this example for the Toms Cove area of Assateague National Seashore, areas of inundation (RCP 4.5 2050) are shown in blue. Other low-lying areas that are blocked from inundation by some impediment are shown in green.

**Storm Surge Data**

NOAA SLOSH data estimate potential storm surge height (NOAA 2016). The NOAA SLOSH model is comprised of the following three products (P-Surge, MEOW, and MOMs) that utilize three different modeling approaches (probabilistic, deterministic, and composite) to estimate storm surge. P-Surge (also known as the tropical cyclone storm surge probabilities product) uses a probabilistic approach by examining past events to estimate the storm surge generated by a cyclone that is present and within 72-hours of landfall. It statistically evaluates National Hurricane Center data (calculated in part using a deterministic approach) including the official projected cyclone track and historical forecasting errors. It also incorporates astronomical tide calculations and variations in the radius of maximum wind into this estimate. These rates of motion variables are then fit to a Cartesian or polar (depending on the location) grid (Jalesnianski et al. 1992).
The Maximum Envelope of Overwash Water (MEOW) calculates flooding using past P-Surge data to create a composite estimate of the potential storm surge generated by a hypothetical storm. This product generates a worst-case scenario based on a hypothetical storm category that includes forward speed, trajectory of the storm when it strikes the coastline, and initial (mean vs. high) tide level that will also incorporate any historical uncertainty from previous landfall forecasts.

The final SLOSH product is the MOM (Maximum of MEOWs) model. MOM is a further composite approach that uses the forward speed, trajectory, and initial tide level data that is also used by MEOW to create a worst-of-the-worst scenario (or "perfect storm"). Storms are simulated for 32 regions (also known as operational basins, Figure 3) defined by NOAA. Data was imported into ArcGIS using the SLOSH display program. Maps were generated showing storm surge for all possible Saffir-Simpson hurricane categories for each site. While most sites had data for Saffir-Simpson hurricane categories 1–5, a few sites, such as Acadia National Park, were missing the highest category. NOAA did not model this scenario because it is considered extremely unlikely at a location that far north in the Atlantic Ocean.

SLOSH MOM was used to estimate potential storm surge in 79 coastal park units. Unfortunately MOM data do not exist for the remaining 39 units, so we supplemented this with data from Tebaldi et al. 2012 wherever possible. Tebaldi et al. (2012) used 55 long-term tide gauge records to calculate potential sea level and storm surge estimates. We used the current 50-year and 100-yr return level data from their paper for any parks near to a tide gauge. Unfortunately we were unable to use either Tebaldi et al. (2012) or SLOSH MOM data for the Alaskan, Guam, and American Samoa park units.

Storm surge models were combined with the mapped sea level rise data to get a rough idea of how these regions could be exposed to flooding occurring later in the century on top of inundation. We
used historical hurricane data from the International Best Track Archive for Climate Stewardship (IBTrACS; Knapp et al. 2010) to ascertain the highest Saffir-Simpson category hurricane to strike within 10 miles of each park unit. We then used the MOM estimate for a storm surge one category higher than anything that had struck the park historically (based data spanning 1842–2014; Appendix E, Table E3). By using one storm category higher than historical data we hoped to approximate what could happen as storms are expected to be more intense due to anthropogenic climate change in the future (Emanuel 2005, Webster et al. 2005, Mendelsohn et al. 2012). However we would recommend caution in using these combined maps for any detailed planning due to the limitations that will be discussed further in the following section of this report.

Limitations

While every effort has been made to use the best available data and techniques, all projects of this nature have limitations that should be clearly delineated to ensure that these data are interpreted correctly. Every effort has been made to incorporate any parks, such as Harriet Tubman Underground Railroad National Monument, that were established after work began, although some maps might be missing due to lack of available boundary data in new units.

We used a bathtub modeling approach to map the extent of sea level rise and storm surge over every unit. Bathtub modeling simply simulates how high up or inland water will go under different climate scenarios. It does not take into account changes in topography or other environmental or manmade systems that will occur in response to encroaching water. While bathtub models are the most widely used technique for modeling inundation, it is also a more passive technique of simulating how sea level rise will impact a landscape (Storlazzi et al. 2013). Dynamic models could model changes in flow around buildings or estimate how topographic features such as dune systems will migrate in response to inundation and flooding; but dynamic models also vary in their methods, which can be a severe limitation if trying to standardize data for comparison and management.

Even though SLOSH MOM has the widest geographic storm surge coverage of any model in the US, storm surge data are not available for every part of the coastline. Every effort has been made by this project to bridge any gaps where SLOSH MOM does not exist. While the Tebaldi et al. (2012) data cover the California, Oregon, Washington, and southern Alaskan coastlines, they do not cover any information for the northern Alaskan, American Samoan, or Guam coastlines. These coastlines are vulnerable to storm surge but we could not find data that we were satisfied were accurate enough to be included in our mapping efforts. Furthermore, combined sea level and storm surge maps are only intended as a rough guide of how flooding by storm surge on top of permanent inundation due sea level rise and should be used with caution. As more of the coastline becomes inundated we can expect coastal flooding to also change accordingly. The SLOSH model is a probabilistic approach that uses previous storms to estimate future storm surge. It cannot take into account any changes in future basin morphology that could affect the fluid dynamics and propagation of coastal flooding.
SLOSH MOM is modeled using mean sea level (0 m NAVD88) and what NOAA terms “high tide” (which is not tied to the local tidal datum, but is actually a round number based on the average high tide for the region that was modeled). Jalesniakski et al. (1992) estimate surge estimates to be accurate +/- 20%, although Glahn et al. (2009) discuss how others have found the P-Surge model to be more accurate than originally estimated. All of these things must be kept in mind when using these numbers for mapping.

**Land Level Change**

It is important to include changes in land level while interpreting changes in sea level. The IPCC (2013) does not include changes in relative sea level in their calculations of sea-level change. Our sea level rise results do not include how changes in land level will change over time. Land level change is an important variable when calculating relative sea level. Land levels have changed over time in response to numerous factors. Changes in various land-based loadings, such as ice sheets during the last glacial maximum, on the continents has been a significant cause of land level change in the U.S. Post-glacial isostatic rebound is the result of this pressure placed on the Earth's crust by the ice sheets and is still causing land levels to change. Land level can also be altered by other factors such as tectonic shifts particularly along Alaska and continental U.S. Pacific coastline. The aforementioned drivers can often prompt either a relative increase or decrease in land level depending on location. Other factors such as aquifer drawdown and the draining of coastal swamps can create decreases in relative land level.

Quantifying how land levels are changing is difficult given the paucity of data available prior to modern satellite data. This data need will be relieved by the release of a NASA study on land-based movement in 2017 (Nerem per. comm.). This NASA report will provide numbers for land-based movement across the country. These numbers should be incorporated with the sea-level rise numbers in this report once they are released in 2017. These numbers can be combined with the numbers in this report in the following equation (after Lentz et al. 2016):

**Eq. 2**

\[ aE = E_0 - e_i + R \]

Where: \( aE \) is the adjusted elevation, \( E_0 \) is the initial land elevation, \( e_i \) is the future sea level for either 2030, 2050, or 2100, and \( R \) is the current rate of land movement due to isostatic adjustments.

In the interim, tide gauges can provide data regarding changes in land level, but should be used cautiously. We have listed tide gauge data for the rate of change in land level for tide gauges nearest to all units for this study in Appendix E; however, only Fort Pulaski National Monument and Point National Historic Point-Site have a long-term tide gauge on site. This lack of nearby long-term data can limit the accuracy of these numbers if they are applied to sea level change projections for almost all other parks units. Land level changes were only reported for long-term tide gauges that had at least thirty years of data in order to ensure a statistically robust dataset. Based on these limited records we estimate that seven park units are currently experiencing decreasing relative sea levels (Figure 4; Glacier Bay National Park, Glacier Bay Preserve, Katmai National Park, Kenai Fjords

Comment [PG7]: The NOAA gauge is in Golden Gate National Recreation Area
National Park, Lake Clark National Park, Sitka National Historical Park), although we cannot be certain of this number given that many of park units are some distance from a tide gauge. We expect the release of the NASA data (Nerem per comm.) to help refine these estimates. 

**Figure 4.** The estimated percentage of park units that currently experience decreasing relative sea levels (orange) versus those with increasing relative sea level (blue).

It is strongly recommended that you discuss the applicability of these land level numbers with a natural resources manager or similar expert to ensure that the nearest tide gauge to your project site is appropriate. In selecting an appropriate tide gauge to use a number of variables must be taken including oceanographic setting, length of the record, completeness of data, and geography of the coastline. A decision was made by the science team for this project to not set a threshold for how close a park unit should be to a long-term tide gauge based on the aforementioned considerations.

Where to Access the Data

All GIS data from this project will be uploaded on www.irma.gov for archiving by park. Non-GIS users can access the data discussed in this report using our online map viewer at:

https://www.nps.gov/subjects/climatechange/sealevelchange

A website discussing this project is available at the following address:

https://www.nps.gov/subjects/climatechange/sealevelchange

The raw IPCC (2013) data can be downloaded using the following link:

http://ipcc.ch/report/ar5/wg1/docs/ar5_wg1_ch13sm_datafiles.zip
Results

Sea level and storm surge maps are in Appendices A and B. A full list of the 118 park units used for this study can be found in Appendix D along with a table listing sea level rise projections per park unit. Following the methods outlined above we found that sea level rise will average between 0.45m (RCP2.6) and 0.67 m (RCP8.5) by 2100. However, this number masks how these data projections will vary geographically. Figure 5 describes these data projections in more detail by breaking down sea level estimates by region. The error bars in Figure 5 denote the standard deviation for each average per region, which further reveals how these numbers can vary. A high standard deviation and range signals that sea level estimates vary between units, whereas a low standard deviation and small range are be expected in smaller regions where sea level rise estimates do not cover such a large geographic area.

Based on the averages per region we found that the shoreline within the National Capital Region is expected to experience the highest sea level rise (0.80 m RCP8.5 2100), although this number does not include changes in land level over the same time interval. The shoreline near Wright Brothers National Memorial in the Southeast Region has the highest overall projected sea level rise (0.82 m RCP8.5 2100). Glacier Bay Preserve and Klondike Gold Rush National Historical Park are tied for lowest projected sea level rise at 0.33 m using RCP8.5 for 2100. The Alaska Region also has the highest standard deviation among park units. The National Capital Region conversely has very little standard deviation due to the compact nature of the region that meant that all of the parks units listed fell within the same raster cell. This is not to say that all of the parks will experience exactly the same amount of sea level rise, but that the IPCC model projected that sea levels could rise up to an average 0.80 m (RCP8.5) above waterline for that region by 2100. These differences among the
National Capital parks is illustrated in our sea level rise maps which will be discussed in further detail in the National Capital section of this report.

Comparing RCP8.5 data for 2030 and 2050 (Figures 4 and 5, respectively) shows the National Capital Region tied with the Northeast Region in 2030 based on average projected sea level rise, however the National Capital Region ranks highest in 2050. The Alaska Region ranks lowest for all three time intervals followed by the Pacific Northwest region, Intermountain Region, and Southeast Region. The Northeast Region comes ranks second highest for 2050 and 2100.

**Figure 6.** Projected future sea level by region for 2030 under RCP8.5. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each average. Blue bars mark the full range of sea level estimates for each region.

**Figure 7.** Projected future sea level by region for 2050 under RCP8.5. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each average. Blue bars mark the full range of sea level estimates for each region.
Storm surge was mapped for 79 park units. Storm surge data were combined with sea level rise projections to approximate how much area could be exposed to flooding on top of inundation. We used data for one storm category higher than the highest historical storm for our combined maps. Table E3 in Appendix E lists the highest historical storm for each park unit. 31 park units did not have a historical storm path travel within 10 miles of their boundaries, so a Saffir-Simpson hurricane 1 was simulated for these locations. The lack of a historical storm does not mean that these parks are not subject to strong storms. It may merely be that these parks are in regions that either do not have extensive historical records or they experience strong storms that are classified differently, such as nor’easters.

The Southeast Region has the strongest historical storms (average of highest recorded storm categories = 2.79), followed by the Intermountain Region (average = 2.33), National Capital Region (average = 1.90), and the Northeast (average = 1.03). None of the historical data intersected with the 10 miles buffers around the Alaska region parks. The Pacific West Region has experienced some tropical depressions, particularly in Hawaii, but most of their storm surges are driven by other phenomena, such as midlatitude cyclones or extreme tides (sometimes colloquially referred to as a king tide). The strongest (highest winds) and most intense (lowest pressure at landfall) recorded historical storm to have impacted a park unit was the “Labor Day Hurricane” that passed within 10 miles of Everglades National Park in 1935. However, while this storm may have been the highest intensity storm it is certainly not the most damaging or costly storm in National Park Service history.

Northeast Region

Figure 8 shows how the range of sea level projections for the Northeast Region for 2100. It is projected to average between 0.49 m (RCP2.6) and 0.74 m (RCP) of sea level rise by the end of the century. Colonial National Historical Park, Fort Monroe National Monument, and Petersburg National Battlefield are all tied for the coastline with the highest projected sea level rise in 2050 and 2100. They are also tied along with Edgar Allen Poe National Historic Site, Fort McHenry National Monument and Historic Shrine, Independence National Historical Park, and Thaddeus Kosciusko National Memorial as parks near coastline with the highest projected sea level rise for 2030. However, while these parks may have ranked highly, so caution should be used when analyzing these results. Many of these parks do not have coastline and so these projections are based on sea level rise for the coastline adjacent to these parks. The maps in Appendix A show how these projected numbers will impact each of these parks. Colonial National Historical Park, Fort McHenry, and Fort Monroe National Monument are the only park units that contain coastline with their boundaries. Acadia National Park had the lowest projected rates of sea level rise for 2030 (0.08–0.10 m), 2050 (0.14–0.19 m), and 2100 (0.28–0.54).
Figure 8. Projected future sea level by 2100 for the Northeast Region under all of the representative concentration pathways. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each average. Blue bars mark the full range of sea level estimates for each category.

The highest recorded storm to have travelled within 10 miles of any of the 29 parks units identified for study was an officially unnamed hurricane in 1869 known colloquially as Saxby’s Gale that was classified as a Saffir-Simpson 3 hurricane. The storm path passed Boston National Historical Park and Roger Williams National Memorial. Figure 9 shows the estimated extent of a storm surge from category 3 hurricane striking Boston Harbor Islands National Recreation Area at mean tide.

Figure 9. Estimated storm surge created by Saffir-Simpson category 3 hurricane occurring at mean tide near Boston Harbor Islands National Recreation Area.
Southeast Region

The southeast region can expect to have some of the more intense (highest Saffir-Simpson storm category) storm over this century. Historically, the region has the highest intensity storms; although Everglades National Park has recorded a category 5 hurricane within 10 miles of its boundary, Figure 10 shows how it would only need to be struck by category 2 hurricane to completely flood the park.

Combining such large storm surges with sea level rise highlights how exposed many of the Southeast Region park units are. It should also be considered that sea level rise projections do not include changes in land level. We recommend waiting for the forthcoming NASA report (Nerem per comm.) on land level before applying any numbers for planning; however, using table E1 from Appendix E as a rough guide changing land level for parks near tide gauges can be evaluated. The Eugene Island, Louisiana tide gauge’s current rate of sea level rise is the highest in the country at 9.65 mm/yr owing in part to the large rate of subsidence in the region (Figure 1). Using the nearest tide gauge to Jean Lafitte National Historical Park and Preserve (Grand Isle, Louisiana, gauge 8761724) we can estimate that land will subside by 7.60 mm/yr. Applying this estimate of subsidence (using a baseline of 1992) to our RCP8.5 projections, the park could experience approximately 0.41 m of relative sea level rise by 2030 followed by 0.69 m by 2050 and 1.50 m by 2100.
Our projections list Wright Brothers National Memorial’s nearest coastline as having the greatest sea
evel rise by 2100 (0.82 m RCP8.5), but given the elevation of the park, this will still not inundate a
large area of the memorial. However this could be more of a problem if this rise in water level is
combined with other factors, such as a storm surge. The park will be almost completely flooded if a
category 2 or higher hurricane strikes on top of the inundation from sea level rise.

Nearby Cape Hatteras and Cape Lookout National Seashores are projected to experience up to 0.79
m and 0.76 m, respectively (RCP8.5) of sea level rise by 2100. Both of the aforementioned units
have shoreline as part of their boundaries, which means these rises in sea level will result in large
areas of inundation. While these national seashores may rank slightly lower than Wright Brothers
National Memorial for sea level rise, they serve as example of how caution must be used when using
these numbers to assess which park units are most vulnerable to sea level rise. Other factors, such as
percent of exposed land, changes in land movement, and adaptive capacity must also be taken into
account for vulnerability analysis (Peek et al. 2015).

National Capital

National Capital Region has very little variability in projected sea level rise because all of the park
units selected for study are all adjacent to the same section of coastline that was modeled. Their
proximity also explains why they all share the same storm history. Despite these similarities, the way
these numbers will impact each individual park unit will vary based on the topography of
Washington D.C. The strongest storm to ever pass within 10 miles of the National Capital Region
parks was as Saffir-Simpson category 2 hurricane that struck the city in 1878. While 1878 storm
caus ed relatively little damage, we can expect a significantly larger amount of damage if a similar
storm struck the city again. Figure 11 shows the extent of flooding created a Saffir-Simpson category
2 hurricane. A storm surge measuring more than 3 m could travel up the Potomac River causing large
amounts of flooding.
IPCC/SLOSH models showed either storm surge or sea level rise (or some combination of the two) impacting every park nominated for study with the exception of Harpers Ferry National Historical Park. Our mapping efforts revealed that Harpers Ferry National Historical Park located approximately 149 m above sea level is unlikely to experience any impacts of sea level rise due to its elevation and is unlikely to be damaged by storm surge from a hurricane from its relatively protected location behind several dams along the Potomac and Shenandoah Rivers. Harpers Ferry is potentially vulnerable to other climate change impacts, such as changing temperatures and precipitation. Sea level rise alone is not expected to spread very far into Washington D.C., although a large section on the east side of Theodore Roosevelt Island will could be inundated. However, storm surge flooding on top of this sea level rise would have widespread impacts.

**Intermountain Region**

The Intermountain Region covers mostly inland park units stretching from Texas to Montana. Only three park units in Texas could be nominated for a study of this nature: Big Thicket National Preserve, Palo Alto Battlefield National Historical Park, and Padre Island National Seashore. Padre
Island National Seashore is likely to experience the greatest effects of sea level and storm surge out of the three park units. Sea level is projected to rise 0.46−0.69 m (RCP2.6−8.5, Figure 12) by 2100. The same amount of sea level rise is projected for the shoreline near Palo Alto Battlefield National Historical Park, but it is not expected to stretch inland enough to reach the park. Palo Alto Battlefield National Historical Park has no history of being within 10 miles of any hurricane, making the site unlikely to be flooded by storm surge. SLOSH MOM models for the park unit show that that the region would have to have either a Saffir-Simpson category 4 hurricane striking at high tide or a category 5 hurricane striking at any tide in order for the park to experience any storm surge. Whereas Figure 13 shows how Padre Island National Seashore located on the shoreline to the east of Palo Alto Battlefield National Historical Park has been within 10 miles of a category 4 hurricane. SLOSH MOM data show that another category 4 hurricane that would likely flood almost the entire island if it struck again.

There is some potential for storm surge to travel up the Neches River and flood the southernmost part of Big Thicket National Preserve, although storm surge defenses in Beaumont, Texas to the south of the preserve are likely to buffer it from any surge. It is more likely that a hurricane would cause flooding over a wider area of the park via precipitation.

**Figure 12.** Projected future sea level by 2100 for the Northeast Region under all of the representative concentration pathways. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each average. Blue bars mark the full range of sea level estimates for each category.
Pacific West Region

The Pacific West Region identified 24 park units that could be vulnerable to sea level rise and/or storm surge. These units are located over a large area comprising California, Oregon, Washington, Hawaii, American Samoa, and Guam. The average projected sea level rise range is between 0.40–0.58 m (RCP2.6–8.5) by 2100 for the whole region; however, there is a large standard deviation between these numbers (0.04 m and 0.08 m for RCP2.6 and RCP–8.5, respectively) that belies how the park-specific projections vary across the region. War in Pacific National Historical Park in Guam has the highest projected sea level rise at 0.68 m (RCP8.5) by 2100. War in Pacific National Historical Park is also tied for highest projected sea level rise with almost all of the Hawaiian park units in 2030 and 2050.

At the other end of the spectrum the park units located around Washington’s Olympic Peninsula (Ebey’s Landing National Historical Reserve, Olympic National Park, and San Juan Island Historical Park) rank lowest for projected sea level rise. Sea level is projected to rise much more slowly in this region reaching a maximum 0.46 m (RCP8.5) by 2100. This is a region that is subject to tectonic shifts as well as continuing land movement due to isostatic rebound that further complicate sea level projections. Long-term tide gauge records at Neah Bay, Washington (gauge 9443090) and Tofino,
Canada (gauge 822-116) show relative sea levels as currently decreasing while tide gauges in Port Angeles, Washington (gauge 9444090), Victoria, Canada (gauge 822-101), and Seattle, Washington (gauge 9447130) show it to be increasing (Zervas 2009). Our projections show sea level in this region to rise throughout this century, although the release of the forthcoming NASA report (Nerem per comm.) could shed more light on this matter.

Modeling for storm surge is complicated by the lack of hurricanes to have stuck many of the parks in this region. Instead we chose to use data from Tebaldi et al. (2012) that includes anomalous surges that could be created by storms as well as other factors (sometimes referred to as king tides). Based on the Tebaldi et al. (2012) data, La Jolla, California (gauge 9410230) has the lowest 100-year storm surge measuring 0.95 m and Toke Point, Washington (gauge 9440910) has the highest 100-year storm surge (1.96 m) in the Pacific West Region. Tebaldi et al. (2012) did not analyze storm data for Hawaii, Guam, or American Samoa, although IBTrACS (Knapp et al. 2010) does have hurricane records for these areas. Only tropical depressions have been recorded within 10 miles almost all of the selected Hawaiian park units (Haleakala National Park, Hawaii Volcanoes National Park, Kalaupapa National Historical Park, Kaloko-Honokohau National Historical Park, Puukohola Heiau National Historic Site, and World War II Valor in the Pacific National Monument).

Alaska Region
The Alaska Region has the lowest average projected sea level rise (0.28–0.43 m by 2100) compared to the five regions described above. Glacier Bay National Park and Preserve and Klondike Gold Rush National Historical Park in southeastern Alaska share the lowest projected sea level rise (0.33 m RCP8.5 2100) while Bering Land Bridge National Preserve on the west coast of the state has the highest projected sea level rise (0.60 m RCP8.5 2100).

Figure 1 shows how current relative sea levels vary across the state. Land levels are rapidly rising in the southeast of the region due to isostatic rebound and other tectonic shifts. Current rates of relative sea level change in Skagway, Alaska are the lowest in the country; decreasing at an average rate of 17.59 mm/yr (Zervas 2009). The net result of these increasing land levels is decreasing relative sea levels for at least the early part of this century. Despite melting ice and other factors outlined in Table 1 that are adding to our ocean waters volume, the amount of rising water is not sufficient to keep up with the land level. Seven park units (Glacier Bay National Park, Glacier Bay Preserve, Katmai National Park, Kenai Fjords National Park, Lake Clark National Park, Sitka National Historical Park) have been identified as potentially having decreasing relative sea levels based on the nearest tide gauge data to each of these parks. None of these parks have long-term tides gauges that have data spanning at least thirty years. A great strength of using the IPCC (2013) process-based model approach is that, unlike many other semi-empirical models, it does not rely on long-term tide gauge records to statistically predict future sea levels. However, our sea level projections do not at this time include changes in land level. The numbers we supply here are for how much we can expect the water volume to rise near to each of these park units. Table E1 shows how land levels are changing at long-term tide gauges across the country. However, given that all of these park units are located far
from a tide gauge and that the region is relatively geologically complex, we would not recommend
using the land movement numbers from the nearest tide gauge for any of the Alaskan parks.

Storm surge is also very difficult to model for this region. Historically, many of the parks had sea ice
along the coastline that helped protect these parks from storm surge. Consequently NOAA does not
have SLOSH MOM models for this region. IBTrACS data (Knapp et al. 2010) show a few storm
paths that have moved towards the region, but these types of storms typically do not make landfall
once they move over colder waters. Alaska does hold the record for the highest intensity (lowest
central pressure) storm (Duff 2015). A downgraded super typhoon, Nuri, struck Adak Island, Alaska
in 2014 with recorded winds gusting up to 122 mph. It is unfortunately impossible to determine an
average or peak historical storm surge without adequate tide gauge data.

Discussion

Global mean sea levels have been rising since the last glacial maximum (Lambeck and Chappell
century global sea levels rose at a rate of approximately 1.7 mm/yr, although this rate accelerated
over the later part of the century. Slangan et al. (2016) found that the release of anthropogenic
greenhouse gases has been the primary driver of global sea level change since 1970 as the rate of sea
level rise has increased over time (Table 1). Satellite altimetry data shows that present-day global
relative sea levels are increasing at approximately 3.3 mm/yr (Cazenave et al. 2014, Fasullo et al.
2016).

The IPCC (2013) expects projects this rate will increase and predicts projects global average sea
levels to increase by 0.40–0.63 m (RCP2.6–8.5) by 2100. We used regional sea level projections
from the IPCC (2013) generated for 2050 and 2100 in combination with our own downscaled
projections for 2030 to estimate how much sea level rise 118 coastal national park units could
experience in the future. Our are projections are based on the new representative concentration
pathways (Meinshausen Moss et al. 2010, Figure 14) and use a process based model approach.

Figure 14: Radiative forcing for each of the Representative Concentration Pathways (RCPs). RCPs replace the IPCC SRES
scenarios. Note how RCP4.5 (yellow line) projections are higher than RCP6.0 (gray line) in the early part of this century.
There are numerous academic articles that use mostly semi-empirical models (Rahmstorf 2007) to estimate sea level rise for a number of regions across the U.S. The IPCC (2013) lists a number of semi-empirical sea level estimates, all of which create estimates of future sea level that are higher than the IPCC (2013) approach. The differences to these approaches can be attributed to a number of factors. For example, some of the older papers may have higher sea level estimates because they are based on the older IPCC SCRES scenarios (e.g. Vermeer and Rahmstorf 2009, Grinsted et al. 2010, Jevrejeva et al. 2010). Other papers may augment their sea level projections with “expert elicitations” where experts are polled on how much they think sea level (or a related factor) could rise in the future (e.g. Bamber and Aspinall 2013, Jevrejeva et al. 2014, Horton et al. 2014). Others have published articles criticizing the IPCC sea level estimates as being too conservative or underestimating rates of future sea level change (e.g. Kerr 2013, Horton et al. 2014). These criticisms were addressed by Church et al. (2013) and so they will not be discussed in detail here. Recent analyses by Clark et al. (2015) further supports the findings of the IPCC.

A key strength of these methods has been that this research applies a unified approach to identify how sea level change will impact all coastal park units across the National Park System, rather than relying on sea level data generated for specific regions. Our analyses revealed that the National Capital Region is projected to be the region to experience the greatest increase in sea level (not taking into account changes in land level). This rise will impact each of the region’s units in different ways depending on the elevation of the individual unit, but it could be catastrophic if combined with a storm surge from a storm such as the category 2 hurricane in 1878.

At the individual park level IPCC projections reveal the sea level along the coastline adjacent to Wright Brothers National Memorial could rise up 0.82 m (RCP8.5) by 2100, which could lead to significant flooding if combined with a storm surge. The Southeast Region as a whole is generally susceptible to inundation and flooding due to its low-lying nature in many places, particularly in the Cape Hatteras/Cape Lookout National Seashores region. Our sea level rise maps highlight how much all of these park units will be impacted.

However these estimates do not factor in changing land levels. We are expecting the latest state-of-the-art land level estimates to be released by NASA in 2017. In the meantime we can roughly estimate relative sea level change for a small number of parks based on current rates of subsidence gathered from nearby long-term tide gauge data. We expect Jean Lafitte National Historical Park and Preserve to have the greatest relative sea level increase based on the current rate of land movement. Our sea level projections agree with current sea level trends that the southeast Alaska region is experiencing the least amount of sea level rise of anywhere in the National Park System.

Sallenger et al. (2012) discussed how storm surge combined with sea level rise could create a 1000-km long “hotspot” along the North Atlantic coast from Cape Cod, Massachusetts to Cape Hatteras, North Carolina. Our projections also found that to be the case. We mapped future inundation caused...
by sea level change combined with flooding caused by a storm measuring one storm category higher than historical for each park unit, assuming an intensification of future storm surge (Webster 2005, Mingfang 2015). We found that almost all of the coastal park units would be flooded under these conditions.

It is unknown exactly to what degree future storm surge will impact the Alaskan park units. Accurate long-term (>30 years) storm surge data do not exist for the Alaska region. Even if such data did exist it would be not be analogous to future conditions in the regions as sea ice that had previously protected the shores for many of the western Alaska park units melts to reveal an easily erodible coastline (Frey et al. 2015). The warming of ocean waters in the Gulf of Alaska and Pacific Ocean could also make it more conducive for more storms like Typhoon Nuri to travel north without losing as energy as they once did.

The Pacific West Region shows a lot of variability among parks. A recent report by Golden Gate National Recreation Area (2016) goes into detail regarding what some of these park units are doing to plan for climate change. The National Research Council report for California, Washington, and Oregon (2012) has been cited frequently as a resource on sea level rise in the region, but it does not cover the entire administrative region that is managed by the Pacific West Region. War in Pacific National Historical Park in Guam ranks first as having the highest projected sea level rise amongst the units administered by the Pacific West Region.

Island park units in general are especially exposed to the impacts of sea level change and storm surge. Many of the barrier island parks, such as Fire Island National Seashore, Assateague National Seashore, Palo Alto Battlefield National Historical Park, Gulf Islands National Seashore and Cape Hatteras National Seashore are all projected to experience sea level rises over 0.69 m by 2100 (RCP8.5). This sea level rise combined with storm surge could be especially difficult for isolated island park units, such as the Caribbean park units, National Park of American Samoa, and War in Pacific National Historical Park where access to aid in the event of a natural disaster may not be immediately available.

**Conclusions**

Projections of sea level change and storm surge due to anthropogenic climate change in 118 coastal park units administered by the National Park Service are presented in this report. Historical storm surge data showed the Southeast Region to have experienced the most intense hurricanes, which could lead to even greater storm surges in the future if storms become stronger (Webster 2005, Mingfang 2015). Sea level rise is projected to generally be greatest in the National Capital Region, although some low-lying parks, such as Everglades National Park and park units in the Outer Banks of North Carolina and Gulf Coast will continue to be challenged by this issue.

Sea level and storm surge will vary geographically, resulting in unique challenges for adaptation and management. It is important to acknowledge that sea level change will impact some parts of Alaska.
differently to the rest of the country. Northwest Alaska can expect relative sea levels to increase over time, while southeast Alaska relative sea levels will likely continue to decrease over the first part of this century followed by an increase in relative sea level by the end of the century.

This project is an important first step in assessing how changes in sea level and storm surge due to anthropogenic climate change will impact our national park units. By combining projected sea level with storm surge data we can start to examine how these two separate variables can exacerbate the impact of each other over time. It is clear that more research can be done on these complex issues to assess how these changes will impact individual parks as well as the wider regions. Looking ahead, these data have applications for a number of future projects related to both natural and cultural resources as well as the planning and management of infrastructure.

Appendix C

Frequently Asked Questions

Q. How were the parks in this project selected?
A. Parks were selected after consultation with regional managers. Regional managers were given a list of parks that authors considered to be vulnerable to sea level change and/or storm surge. This list was vetted by regional managers and their staff who added or subtracted park names based on their knowledge of the region.

Q. Who originally identified which park units should be used in this study?
A. The initial list of parks was approved by the following regional managers: Northeast Region, Amanda Babson (signed 11/27/13); Southeast Region, Shawn Benge (signed 11/14/13); National Capital Region, Perry Wheelock (signed 3/17/14); Intermountain Region, Patrick Malone signed on behalf of Tammy Whittington (signed 11/13/13); Pacific Region, Jay Goldsmith (signed 11/26/13); Alaska Region, Robert Winfree (signed 11/15/13).

Q. What’s the timeline of this project?
A. This is the culmination of a three-year project that was proposed in February 2012. Initial Fiscal year of funding was 2013.

Q. Where did you use data used by Tebaldi et al. (2012)?
A. NOAA’s Sea Lake and Overland Surge from Hurricanes (SLOSH) model does not include storm surge predictions for all of the parks used in this study. We used data from Tebaldi et al. (2012) where reasonable to help plug some of these gaps in our data network for park units in California, Oregon, Washington, and southern Alaska.

Q. Why don’t all of the parks have storm surge maps?
A. Unfortunately some parks do not have enough data to complete a storm surge map. These were parks that were not modeled by NOAA’s SLOSH MOM model or near any of the tide gauges used by Tebaldi et al. (2012). The following parks used Tebaldi et al. (2012) data: Klondike Gold Rush National Historical Park, Lewis and Clark National Historical Park, Olympic National Park, Port Chicago Naval Magazine National Scenic Trail, Point Reyes National Seashore, Redwood National Park, San Francisco Maritime National Historical Park, San Juan Island National Historical Park, and Santa Monica Mountains National Recreation Area.

Q. My park only has storm surge maps covering a few Saffir-Simpson categories. Why is that?
A. Some parks, particularly those in the Northeast Region, were not modeled by NOAA for the full range of Saffir-Simpson storm scenarios. This is because it is considered very unlikely that a Saffir-Simpson category 4 or 5 hurricane would be able to sustain itself into that region.
Q. Why are the storm surge maps in NAVD88?
That is the default datum for SLOSH data. This was a decision made by NOAA.

Q. What are the effects of NAVD88 on projections for some parks?
The North American Vertical Datum of 1988 (NAVD88) is a datum that is commonly used in North America. It uses a fixed value for the height of the sea level. While this is a popular datum for mapping, it has the limitation that it is based on the tidal benchmark for Rimouski, Canada. As you move further away from this benchmark you can expect actual sea level to differ from the reference benchmark. For locations such as California this can result in a significant difference between observed mean sea level and NAVD88. Your natural resource or GIS specialist will likely have further information about your specific location. Alternatively you can look up the differences in your region by checking the datum information for your nearest tide gauge station: [https://tidesandcurrents.noaa.gov/stations.html?type=Datums](https://tidesandcurrents.noaa.gov/stations.html?type=Datums)

Q. Which sea level change or storm surge scenario would you recommend I use?
All parks are different, as are all projects. Your choice of scenario may depend on many different factors. The NPS has not yet released any guidance on which climate change scenarios to use for planning. We would recommend you contact the appropriate project lead, natural or cultural resource manager, or someone from the Climate Change Response Program for further guidance depending on your situation.

Q. How accurate are these numbers?
A. The accuracy of these data varies depending on the data source. SLOSH data has +/- 20% accuracy, although this is discussed in greater detail by Glahn et al. 2009. Further information about storm surge data generated by Tebaldi et al. can be found in Tebaldi et al. (2012). The standard error of the IPCC is explained in greater detail in the chapter 13 supplementary material in AR5 (IPCC 2013).

Q. We have had higher/lower storm surge numbers in the past. Why?
A. The numbers given here are meant to represent an average storm surge number. As described above there is likely to be some deviation around that number. Certain periods are also likely to result in higher than average storm surges. For example, El Niño and La Niña years will impact sea level. Likewise, changes in the North Atlantic Oscillation and Pacific Decadal Oscillation will also affect ocean conditions. This must be taken into account when using these numbers. All of these factors vary temporally and geographically, so contact your natural resource manager if you are unsure how this could impact your particular park unit.

Q. What other factors should I consider when looking at these numbers?
A. These projections do not include the impact of man-made structures, such as levees and dams. They also do not take into account how smaller features, such as dune systems or vegetation changes

Comment [PG9]: It would be good to give ranges of the IPCC standard errors.
could impact coastal flooding. There are many meso- and micro-scale factors that need to be taken into account such as differences in topography, the presence/absence of any wetlands etc. It should also be expected that as sea levels change, areas of the shoreline will change accordingly, particularly due to erosion and accretion.

Q. Why don’t you recommend that I add storm surge numbers on top of the sea level change numbers?

A. Sea level change is expected to have a significant impact on the geomorphology of the coastline. Changing water levels will lead to areas of greater erosion in some areas as well as increasing accretion in other places. Permanent inundation will change the way waves propagate within a basin in the future. As sea level changes, the fluid dynamics of a particular region will also change. This is not something NOAA takes into account in their SLOSH model.

Q. Where can I get more information about the sea level models used in this study?

Q. Where can I get more information about the NOAA SLOSH model?

A. http://www.nhc.noaa.gov/surge/slosh.php

Q. So, based on your maps, can I assume that my location will stay dry in the future?

A. No. As explained above, these numbers are accurate within a certain range. Also, these maps are based on “bath tub” models where water is simulated as rising over a static surface. In reality, your coastline will change in response to storms and other coastal dynamics. These numbers are intended for guidance only.

Q. Why do you use the period 1986–2005 as a baseline for your sea level rise projections?

A. We are following the standard approach used by the IPCC, USACE, and much of the academic literature. If you would like your estimate to start from a specific year you can do one of two things: 1) subtract the observed rate of sea level rise since 1992 for your location, or 2) contact Rebecca Beavers for assistance. It may be possible to downscale projections further to estimate the amount of rise the models estimate to have taken place between the baseline and whichever year you choose. We must caution that if you follow option 1 you will be introducing some inaccuracy to sea level projections, especially if you use data from a tide gauge that is not close to your location.

Q. The SLOSH/IPCC projections seem lower/higher than X source I’ve found. Why is that?

A. Projections can vary depending on a number of factors such as choice of model, approach, or the age of the study. We would recommend that you speak to a climate specialist when choosing between sources.

Q. What are other impacts from sea-level rise that parks should consider?
A. Impacts from sea-level rise could include, but are not limited to, destroyed cultural resources, damage to above ground infrastructure, difficulty accessing buried infrastructure, increased groundwater intrusion, altered groundwater salinity, diminished space for recreational activities (possibly leading to conflict between different recreational users), and the complete loss or migration of certain coastal ecosystems.
Appendix D

Waysides

The following pages show the final designs for waysides that were installed in parks as part of the funding for this project. Gulf Islands National Seashore received two waysides that were received in 2015. Jean Lafitte National Historical Park and Preserve and Fire Island National Seashores waysides were installed in 2016.
See Change...

The earth's climate is changing, raising sea level and increasing the frequency of storm surges. Erosion and rising sea level change the shape and size of barrier islands and mainland shorelines along the Gulf Coast. The roots of coastal plants slow erosion by anchoring the land. As sea level rises, increased salt content in the soil will kill the plants leaving the land exposed to more erosion. In many places, the amount of dry land is decreasing at a significant rate.

The Gulf Coast draws millions of visitors to relax in the bright sun, play in the crystal blue surf, explore the snow white beaches, and watch for wildlife. Yet, this dry land, at the edge of rising waters, could be claimed by the Gulf of Mexico forever.

Gulf Islands National Seashore is investing in energy efficient equipment and seeking new sustainable solutions to help keep these shores from disappearing beneath the rising sea.

- beach grass on coastal developments and rising sea level impact the nesting beach habitat of sea turtles. Which turtle species is ready to lay her eggs?
- please join the National effort in protecting these beaches, and you and your children may watch her hatchlings return to lay their eggs.
See Change...

The earth’s climate is changing, raising sea level and increasing the frequency of storm surges. Erosion and rising sea level change the shape and size of barrier islands and mainland shorelines along the Gulf Coast.

The roots of coastal plants slow erosion by anchoring the land. As sea level rises, increased salt content in the soil will kill the plants letting the land exposed to more erosion. In many places, the amount of dry land is decreasing at a significant rate.

Fighting the Rising Sea

Each year, erosion, storms, shipping channels, and rising sea level are changing the shoreline of the barrier islands. The National Park Service and the Corps of Engineers work together on an outreach program to rebuild the seawalls around historic Fort Massachusetts. The Fort is often battered by waves, putting the structure in jeopardy.

Please join the National Park Service in protecting our seashores so that you and your children may continue to enjoy these historic places.

The Gulf Coast draws millions of visitors to relax in the bright sun, play in the crystal blue surf, explore the historic forts, and watch for wildlife. Yet, this dry land, at the edge of rising waters, could be claimed by the Gulf of Mexico forever.

Gulf Islands National Seashore is investing in energy efficient equipment and seeking new sustainable solutions to help keep these shores from disappearing beneath the rising sea.
Sinking Land, Rising Water

This is the Barataria Basin, built of soil washed to this area by the Mississippi River. This soil is still compacting and sinking, a process called subsidence. Most of the Barataria Preserve is less than two feet above sea level, and its subsidence rate is nearly half an inch a year.

Meanwhile, glaciers and polar ice sheets are melting and our warming climate is heating oceans everywhere, making their waters expand just like water does when you heat it on the stove. Everywhere on the planet, the oceans are a little higher every day.

The combination of the Barataria Basin’s sinking land and global sea level rise means that the ocean is creeping in faster here than almost anywhere else in North America.

- Floods are becoming more frequent and lasting longer
- Coastal wetlands are disappearing as land sinks and water rises
- Less land is available to buffer Gulf of Mexico storms
- Storm and flooding threats to homes, communities, and infrastructure like highways, ports, and energy facilities are increasing
- Salt water from the Gulf is moving into freshwater wetlands, killing the plants that hold the land together
- Death of plants, animals, and microbes that cannot tolerate increased flooding or salt water

The photo shows two images: one of flooding on Barataria Basin after Hurricane Isaac in August 2012. The map shows projected flooding in 2050, and the numbers in the preserve blue area would be flooded and show an increased elevation.
See Change In A Changing Climate

Natural landscape change can be nearly imperceptible on a barrier island, as the wind and waves gradually shape the shoreline, beach, and dunes. Natural changes can also be obvious and happen quickly during storms like hurricanes and nor’easters. Looking ahead, storms will have a greater impact on Fire Island due to climate change.

When we burn fossil fuels, carbon dioxide is released into the atmosphere and acts like a heat trapping blanket around our planet. Heat that would normally escape from the atmosphere is retained, warming the Earth and changing climate patterns. As ocean waters warm and ice on land melts, sea level rises and impacts Fire Island and coastlines all over the world. The future of this barrier island is in jeopardy due to these human-induced climate change effects.

Fire Island protects mainland Long Island against storms and is a stunning setting for recreation, education, and inspiration. It also provides critical habitat for plants and wildlife. We must do what we can to protect this special place. By using renewable energy sources and reducing our dependence on fossil fuels, we can take steps today to preserve barrier island systems and processes, and help build natural resilience to future storms and sea-level rise.

Storm Stories

On October 29, 2012, Hurricane Sandy struck Fire Island National Seashore and changed the way of the land. During the storm, high water and large waves washed sand from the beach and dunes, eroded sand across the width of the island, and erased the beaches, painted here, through the barrier island. The storm was the strongest in recorded history to make landfall in this region.

To learn more about how climate change is impacting the Seashore, please visit www.nps.gov/this/learn/climatechange.htm

1 Number of years used by the USACE to calculate sea level change
(source: [http://www.corpsclimate.us/ccaceslcurves(superseded).cfm](http://www.corpsclimate.us/ccaceslcurves(superseded).cfm))
2 It is not recommended that you use this tide gauge data to determine land level for this park. The boundary is located either too far away or on a different land mass to where the nearest tide gauge is, which increases the inaccuracy of this data. It is strongly recommended that you wait for the forthcoming NASA report on land level (Nerem in prep).
3 The park boundary stretches over either large or multiple areas. More than one tide gauge record is appropriate for this park.
Table E2. Sea level rise numbers by NPS unit. Results are sorted by region. Values are reported in meters. See table footnotes for further details.

1 Parks that do not have shoreline These numbers are for the nearest shoreline to the park
2 † Parks that are likely to be significantly impacted by changes in land level that could result decreasing relative sea level in the short term followed by increased relative sea level by the end of the century Refer to section methods for more information
3
1 No data was available for this scenario. Data from an adjacent cell was used in lieu.

2 Parks that cover two or more cells. Data were averaged between these parks based on percentage of shoreline in each cell.

3 Adjacent cells were used in cases where boundaries crossed into null data cells.
Table E3. IBTrACS data (Knapp et al. 2010) was used to identify the highest recorded storm track to have passed within 10 miles of each of the park units.

Thanks,

Patrick
Thanks for getting this back to me. I really appreciate you taking the time to review this. I know you're very busy at the moment. I'm looking forward to getting this report out and then turning my attention to putting this into an academic publication.

With regards to authorship, would you like to be co-author on this? You've spent so much time working on this giving me advice throughout the life of the project and helping with text.

Cheers,

Maria Caffrey, PhD

On Tue, Oct 4, 2016 at 10:26 PM, Patrick Gonzalez NPS <patrick_gonzalez@nps.gov> wrote:

Hi Maria,

Congratulations on finishing the draft of your technical report! It represents a lot of hard work.

You'll find attached the document with recommended edits tracked in Word. I found no major issues. You'll see that most of the edits related to using the word “projected” for future estimates that are dependent on emissions scenarios and use of the conditional voice (could, might) when talking about the future. I did not have time to add explanatory comments for each edit - I know that you'll easily grasp the rationale behind individual edits. You can call me on my personal cell phone [b] (6) [b] for any questions.

All the best,

Patrick

Patrick,

No problem. You don't need to hurry it. I can wait until Monday. I'm attending the Geological Society of America meeting this week, so I have other things I can do with my time. I just thought I might take a poke at some edits during my downtime between papers.
Hi Patrick,

I’m sorry for the delay in reviewing your report. I travelled, then gave two presentations, then was on leave. If you can wait until tomorrow, I can make suggestions to the Word document though track changes.

Patrick

Hi Patrick,

Do you have any edits you would like to suggest for the final report? I'm starting to make changes based on Amanda's comments, but I wanted to see if you have anything to add before I start going through it.

Cheers,

wrote:

Amanda, Patrick,

Here is the draft report. I have included an excel spreadsheet for your comments so I don't have to try and combine four versions of track changes from everyone (I'll be emailing Rob and Steve for their comments separately). Please try to get your reviews back to me by 9/16/16.

Have a great labor day weekend!

Frequently Asked Questions

Q. How were the parks in this project selected?

A. Parks were selected after consultation with approval of regional managers. Regional managers were given a list of parks that authors considered to be vulnerable to sea level change and/or storm surge. This list was vetted by regional managers and their staff who added or subtracted park names based on their knowledge of the region.

Q. Who originally identified which park units should be used in this study?

A. The initial list of parks was approved by the following regional managers: Northeast Region, Amanda Babson (signed 11/27/13); Southeast Region, Shawn Benge (signed 11/14/13); National Capital Region, Perry Wheelock (signed 3/17/14); Intermountain Region, Patrick Malone signed on behalf of Tammy Whittington (signed 11/13/13); Pacific Region, Jay Goldsmith (signed 11/26/13); Alaska Region, Robert Winfree (signed 11/15/13).

Q. What’s the timeline of this project?

A. This is the culmination of a three-year project that was proposed in February 2012. Initial Fiscal year of funding was 2013.

Q. Where did you use data used by Tebaldi et al. (2012)?

A. NOAA’s Sea Lake and Overland Surge from Hurricanes (SLOSH) model does not include storm surge predictions for all of the parks used in this study. We used data from Tebaldi et al. (2012) where reasonable to help plug some of these gaps in our network for park units in California, Oregon, Washington, and southern Alaska. The following parks used Tebaldi et al. (2012) data: Klondike Gold Rush National Historical Park, Lewis and Clark National Historical Park, Olympic National Park, Port Chicago Naval Magazine National Scenic Trail, Point Reyes National Seashore, Redwood National Park, San Francisco Maritime National Historical Park, San Juan Island National Historical Park, and Santa Monica Mountains National Recreation Area.

Q. Why don’t all of the parks have storm surge maps?

A. Unfortunately some parks do not have enough data to complete a storm surge map. These were parks that were not modeled by NOAA’s SLOSH MOM model or near any of the tide gauges used by Tebaldi et al. (2012). The following parks used Tebaldi et al. (2012) data: Klondike Gold Rush National Historical Park, Lewis and Clark National Historical Park, Olympic National Park, Port Chicago Naval Magazine National Scenic Trail, Point Reyes National Seashore, Redwood National Park, San Francisco Maritime National Historical Park, San Juan Island National Historical Park, and Santa Monica Mountains National Recreation Area. These parks are:

Q. My park only has storm surge maps covering a few Saffir-Simpson categories. Why is that?
A. Some parks, particularly those in the Northeast Region, were not modeled by NOAA for the full range of Saffir-Simpson storm scenarios. This is because it is considered very unlikely that a Saffir-Simpson category 4 or 5 hurricane would be able to sustain itself into that region.

Q. Why are the storm surge maps in NAVD88?

That is the default datum for SLOSH data. This was a decision made by NOAA.

Q. What are the effects of NAVD88 on projections for some parks?

The North American Vertical Datum of 1988 (NAVD88) is a datum that is commonly used in North America. It uses a fixed value for the height of the sea level. While this is a popular datum for mapping, it has the limitation that it is based on the tidal benchmark for Rimouski, Canada. As you move further away from this benchmark you can expect actual sea level to differ from the reference benchmark. For locations such as California this can result in a significant difference between observed mean sea level and NAVD88. Your natural resource or GIS specialist will likely have further information about your specific location. Alternatively you can look up the differences in your region by checking the datum information for your nearest tide gauge station: https://tidesandcurrents.noaa.gov/stations.html?type=Datums

Q. Which sea level change or storm surge scenario would you recommend I use?

All parks are different, as are all projects. Your choice of scenario may depend on many different factors. The NPS has not yet released any guidance on which climate change scenarios to use for planning. We would recommend you contact the appropriate project lead, natural or cultural resource manager, or someone from the Climate Change Response Program for further guidance depending on your situation.

Q. How accurate are these numbers?

A. The accuracy of these data varies depending on the data source. SLOSH data has +/- 20% accuracy, although this is discussed in greater detail by Glahn et al. 2009. Further information about storm surge data generated by Tebaldi et al. can be found in Tebaldi et al. (2012). IPCC global sea level rise projections range between 0.26 m (RCP2.6 minimum likely range) and 0.82m (RCP8.5 maximum likely range) by 2100. The standard error of the IPCC is explained in greater detail in the chapter 13 supplementary material in AR5 (IPCC 2013).

Q. We have had higher/lower storm surge numbers in the past. Why?

A. The numbers given here are meant to represent an average storm surge number. As described above there is likely to be some deviation around that number. Certain periods are also likely to result in higher than average storm surges. For example, El Niño and La Niña years will impact sea level. Likewise, changes in the North Atlantic Oscillation and Pacific Decadal Oscillation will also affect ocean conditions. This must be taken into account when using these numbers. All of these factors vary temporally and geographically, so contact your natural resource manager if you are unsure how this could impact your particular park unit.
Q. What other factors should I consider when looking at these numbers?

A. These projections do not include the impact of man-made structures, such as levees and dams. They also do not take into account how smaller features, such as dune systems or vegetation changes could impact coastal flooding. There are many meso- and micro-scale factors that need to be taken into account such as differences in topography, the presence/absence of any wetlands etc. It should also be expected that as sea levels change, areas of the shoreline will change accordingly, particularly due to erosion and accretion.

Q. Why don't you recommend that I add storm surge numbers on top of the sea level change numbers?

A. Sea level change is expected to have a significant impact on the geomorphology of the coastline. Changing water levels will lead to areas of greater erosion in some areas as well as increasing accretion in other places. Permanent inundation will change the way waves propagate within a basin in the future. As sea level changes, the fluid dynamics of a particular region will also change. This is not something NOAA takes into account in their SLOSH model.

Q. Where can I get more information about the sea level models used in this study?

Q. Where can I get more information about the NOAA SLOSH model?

A. http://www.nhc.noaa.gov/surge/slosh.php

Q. So, based on your maps, can I assume that my location will stay dry in the future?

A. No. As explained above, these numbers are accurate within a certain range. Also, these maps are based on “bath tub” models where water is simulated as rising over a static surface. In reality, your coastline will change in response to storms and other coastal dynamics. These numbers are intended for guidance only.

Q. Why do you use the period 1986–2005 as a baseline for your sea level rise projections?

A. We are following the standard approach used by the IPCC, USACE, and much of the academic literature. If you would like your estimate to start from a specific year you can do one of two things: 1) subtract the observed rate of sea level rise since 1992 for your location, or 2) contact Rebecca Beavenspark, region, or Climate Change Response Program staff for assistance. It may be possible to downscale projections further to estimate the amount of rise the models estimate to have taken place between the baseline and whichever year you choose. We must caution that if you follow option 1 you will be introducing some inaccuracy to sea level projections, especially if you use data from a tide gauge that is not close to your location.

Q. The SLOSH/IPCC-projections seem lower/higher than X source I’ve found. Why is that?
A. Projections can vary depending on a number of factors such as choice of model, approach, or the age of the study. We would recommend that you speak to a climate specialist when choosing between sources.

Q. What are other impacts from sea-level rise that parks should consider?

A. Impacts from sea-level rise could include, but are not limited to, increased erosion, damaged cultural resources, damage to above and below ground infrastructure, difficulty accessing inundated infrastructure, increased groundwater intrusion, altered groundwater salinity, diminished space for recreational activities (possibly leading to conflict between different recreational users), and the complete loss or migration of certain coastal ecosystems. For more information on the topic, please see the Coastal Adaptation Strategies Handbook at: http://www.nps.gov/subjects/climatechange/coastalhandbook.htm

I have a work session with my graduate student researcher 10-1 PDT, then a National Climate Assessment telephone call 1-2:30 PM PDT (5:30 PM EDT) on Friday. Oh no - I am at Golden Gate NRA all day Nov. 9. The only other time then is 9 AM PDT on Friday.

Patrick

To: Patrick Gonzalez NPS <patrick_gonzalez@nps.gov>

Hi Patrick,

I'm afraid Rebecca and Amanda are tied up until 12 PST (1 pm MST, 3 pm EST) on Friday. Do you have any time in your afternoon to talk? I could move it to Wednesday 11/9 if that doesn't work for you.

Amanda would like us to completely remove the combined maps/data. She says that she can't recommend the report to her region if it is not removed.

Cheers,

   Hi Maria,

   On Thursday, I will be on a bus then a train returning from Yosemite. I do not know my schedule yet. Cell phone service is not continuous until the later part of the trip. So, Friday is a better day if possible, perhaps 9 AM PDT - 10 AM MDT - 12 PM EDT.

   If not, I think it would be good to have a panel of three maps: Sea level only, storm surge only, combined.

   Thanks,
Hi Patrick,

I was wondering if you might be available to chat next week with me and Amanda Babson (and maybe Rebecca depending on her availability)? Amanda has some concerns regarding whether we should(b) (5) [redacted]. I know we have discussed this before, but she would like that(b) (5) [redacted].

I think the report should be ready to go out for external review within the next week or so, so it would be good to discuss this issue before it goes out.

Thanks,

Instructions to Reviewers:

You have been asked to review the “Sea Level and Storm Surge Projections for 119 National Park Service Units”. This report will be released as part of a three year project with the University of Colorado. The aim of the report is to combine sea level and storm surge estimates for 118 coastal park units. These sea level and storm surge estimates were generated by the Intergovernmental Panel on Climate Change (IPCC) and the NOAA. You have been chosen as a reviewer because of your expertise in this matter; you are not expected to review to whether using these datasets was an appropriate choice for this project, but we would like you to assess whether there are any technical errors in how these datasets have been applied and discussed.

Some of the data can be viewed using an online viewer: [Online Viewer](https://www.dropbox.com/sh/scfiwntlliasfh0/AAAOMFgFZLoS1jL9_vonekjha?dl=0)

The report itself can be downloaded from: [Report](https://www.dropbox.com/sh/scfiwntlliasfh0/AAAOMFgFZLoS1jL9_vonekjha?dl=0)

The online viewer will undergo separate review. ArcGIS is currently available by request. Use the attached excel spreadsheet to record your comments/suggested edits. Do not make edits in word.

Please return your review to us by COB December 16th.

Thank you for agreeing to review this important dataset.

34 Request review by Dec 14 for NPS SL.SS Report(3).pdf
Hi Doug:

Thank you for your time to consider this review. Please let me know if this is a feasible task for you to complete for the National Park Service. We need one reviewer with experience with applications of SLOSH Results.

Instructions to Reviewers:

I request your review of a report for the National Park Service entitled “Sea Level and Storm Surge Projections for 118 National Park Service Units.” This report will be released as part of a three-year project with the University of Colorado. The report provides sea level and storm surge estimates for 118 coastal park units. These sea level and storm surge estimates were generated by the Intergovernmental Panel on Climate Change (IPCC) and the NOAA. You have been chosen as a reviewer because of your expertise in this matter; you are not expected to review whether using these datasets was an appropriate choice for this project, but we would like you to assess whether there are any technical errors in how these datasets have been applied and discussed.

Some of the data can be viewed using an online viewer:

The report itself can be downloaded from: https://www.dropbox.com/sh/scfjwntlliasfh0/AAAOMFgFZLoS1jL9_vonekiha?dl=0

The online viewer will undergo separate review. ArcGIS is currently available by request. Use the attached excel spreadsheet to record your comments/suggested edits. Please do not make edits in word.

Please return your review by COB December 14th. Early submission of your review would be greatly appreciated.
Cheers,

rebecca

Tebaldi could review the "storm surge data" subsection in the Methods (p 6-8) and the Pacific West region results subset (p 20-21) -- that's where we used her data.

Hi Rebecca,

I got your voicemail. I would be glad to review the report. Your voicemail indicated you wanted me to review the storm surge section. I assume this entire report (link provided) is what you need reviewed?

Was this based on any of the work that Lynda Bell and Jeremy Cantor were doing in NC? We had a call with them a while back.

I may run this by the folks at NHC, if they have time to review. I have been engaging Jamie Rhome about SLR + Surge for other clients too (DHS).

Maria,

I looked it over and thought it looked pretty good, but there was one major thing (#3 below) that I think you should strongly consider changing:

#1. In your List of Terms, it is not common practice to call “sea level change” relative sea level change. Sea level change is a generic term that could be relative sea level change (as measured by a tide gauge) or it could be absolute sea level change (as measured by a satellite altimeter).

#2. I think some readers will find Figures 4-6 misleading, because they will interpret the spread as uncertainty, when they in fact just represent variability in the region. I know you explain this in the text, but some people will just look at the figures.

#3. The IPCC global projections are really given as a range, and you only report the central value. For example, the global projections for RCP8.5 range from 50 cm to 98 cm if I remember correctly. I wouldn’t think of this as an error - it really represents the range of the projections given by the IPCC based on 90% confidence. Without using the ranges, you really aren’t using the IPCC projections correctly. Instead of thinking of it as an error, think of it as the IPCC giving you the 90% probability of where the sea level rise will fall for 2100 (between 50 and 98 cm).

I know the regional projections don’t come with ranges, but you could simply scale them based on the global numbers (e.g. if the central value is 74 cm, then you would multiply the regional numbers by 50/74 to get the low end and 98/74 to get the high end). Perhaps you can add these ranges to the figures.

In effect, you are misrepresenting the IPCC projections, so I feel this is something you should fix (or you will have people criticize your interpretation of the IPCC projections). While this may seem like a major change, I think you can implement it pretty easily. I would just remove Eq 1 and discussion - it’s not important if you use the ranges as I’ve discussed.

Thanks,

Steve

</table>

Im sure you may get this question from other reviewers. Why use the lower IPCC estimates of SLR that really don't take into account more aggressive ice melt scenarios. Most Federal Agencies are/or have agreed to use the Parris et al, 2012 (input to the 3rd National Climate Assessment) scenarios or at least other similar scenarios such as the NRC west coast scenarios or the USACE scenarios. Also these have been used by DOD more recently and updated in their Coastal Assessment Regional Scenario Working Group (CARSWG). [https://www.serdp-estcp.org/content/download/38961/375873/version/3/file/CARSWG+SLR+FINAL+April+2016.pdf](https://www.serdp-estcp.org/content/download/38961/375873/version/3/file/CARSWG+SLR+FINAL+April+2016.pdf) The FEMA TMAC future conditions mapping report points to these scenarios as does the E.O. 13690 - Federal Flood Risk Management Standard (FFRMS) - Climate Informed Science Approach.

It is not very clear if local subsidence was taken into account for all of these sites? The SLR scenarios should be based on locals relative sea level rise. At the very least, choosing closest tide gauge and using the USACE SLR Calculator would result in more accurate local scenarios if you were to use the NCA scenarios, or just use the subsidence values in the equations to extrapolate future sea level rise. I fear not taking into account local subsidence will result in number too low for the future scenarios.

The highest SLR scenario used is the RCP 8.5 by 2100 which only estimates ~0.8m of Sea Level Rise. The upper end of the NCA3 scenarios was 2.0m and the NCA4 range is likekly to go up to 2.5m for the 2100 worse case RCP 8.5 scenario. I think your SLR estimates are too low for future planning.

Please check the descriptions of the P-Surge, MEOWS, and MOMs. P-Surge is used for probabilistic real-time runs during landfalling storms and produces an exceedence probability. The MEOWS and MOMS in the SLOSH display program were not derived from P-Surge and have no probability associated with them. The MEOWS are a worst case basin snapshot for a particular storm category, forward speed, trajectory, and initial tide level, incorporating uncertainty in forecast landfall location. These products are compiled when a SLOSH basin is developed or updated. MEOWs are not storm specific and are available to view in the SLOSH display program for all operational basins. No single hurricane will produce the regional flooding depicted in the MEOWs. Instead, the product is intended to capture the worst case high water value at a particular location for hurricane evacuation planning.

MOMS provide a worst case snapshot for a particular storm category under "perfect" storm conditions. Each MOM considers combinations of forward speed, trajectory, and initial tide level. These products are compiled when a SLOSH basin is developed or updated. As with MEOWs, MOMs are not storm specific and are available to view in the SLOSH display program for all operational basins. No single hurricane will produce the regional flooding depicted in the MOMs. Instead, the product is intended to capture the worst case high water value at a particular location for hurricane evacuation planning. Long story short is that MOMS are used for worse case evacuation planning and are not in any way related to the 100 year or 1% chance storm and thus should not be compared to the Tebaldi et al, 2012
Using MOMs can be problematic because in the SLOSH display program there are often mean tide and high tide runs, but the various basins ran different amounts of tide and different tide scenarios, based on what the State Partners wanted modeled for their state Hurricane Evacuation Study. Also where basins overlap there will be non-matching values. Choosing the correct basin value is often a judgement call. NHC has recently put out a National MOM product and they are working on a version 2 and they plan to make the GIS data available. I suggest you contact NHC and try to access this data to improve your study results.

Tebaldi uses MHW to reference the extreme surge values…and the mapping for the SLR projections was relative to MHHW. Make sure datums are consistent.

SLOSH uses a multiple scenario approach…not probabilistic.

The Storm surge layers were not in the map viewer. I could not find where to download the GIS data. Also I noticed the maps for the high SLR scenario for RCP 8.5 are comparable to the NOAA SLR viewer maps for around 2FT above MHHW. I think this is too low of a scenario for 2100 planning. We have reached 2FT above MHHW during high frequency king tide / perigean tide events in Charleston, SC.

Figure 4. Does this include the Gulf Coast? Seems like the number should be much higher in the Gulf based on the very high SLR trends in Louisiana vs. the East Coast.

Discussion: need to add a description of the difference between using SLOSH MOMs worse case scenarios and Tebaldi numbers for West Coast. These really are not comparable. The Tebaldi numbers are based on the work of NOAA (Zervis) which are based on 1% water levels at the tide gauges. These numbers will also not match FEMA coastal flood studies because wave effects are not included. The SLOSH MOMs are often way higher than the 1% flood. For example, in Charleston, SC the 1% chance water level at the Charleston tide gauge is ~7.5FT. The category 1 MOM is that high. Going out to Cat 2-5 will produce surge value way above the 1% chance. So comparing SLOSH vs. Tebaldi numbers isn’t really valid. One is based on probabilistic analysis of historical data and the other is on 4500 or so scenario runs and having a cumulative peak value. In many cases in the east and gulf coast the 1% chance FEMA BFE is only a Cat 1 to Cat 2 MOM value.

How were the SLOSH results mapped? There are methods out there from the USACE for doing this for HES studies. http://www.northerngulfinstitute.org/impact/resources/inundationWorkshop/scott.pdf

SLR mapping was done using MHHW but was that converted to NAVD88 to match the DEMs? Just wanting to make sure all the map legend values are showing correct height relative to the same datum for both sets of

my comments. I didn't get into the gory details of the numbers etc..in the Appendices but rather looked at it from a more general sense with overarching method comments.

Hope this helps. Let me know if you all have questions.

Hi Doug:

Thank you for your time to consider this review. Please let me know if this is a feasible task for you to complete for the National Park Service. we need one reviewer with experience with applications of SLOSH Results.
Instructions to Reviewers:

I request your review of a report for the National Park Service entitled “Sea Level and Storm Surge Projections for 118 National Park Service Units”. This report will be released as part of a three year project with the University of Colorado. The report provides sea level and storm surge estimates for 118 coastal park units. These sea level and storm surge estimates were generated by the Intergovernmental Panel on Climate Change (IPCC) and the NOAA. You have been chosen as a reviewer because of your expertise in this matter; you are not expected to review to whether using these datasets was an appropriate choice for this project, but we would like you to assess whether there are any technical errors in how these datasets have been applied and discussed.

Some of the data can be viewed using an online viewer: [b] (5) [b] (5)

The report itself can be downloaded from: https://www.dropbox.com/sh/scfjwmtlliasfh0/AAAOMFgFZLoS1jL9_vonekjha?dl=0

The online viewer will undergo separate review. ArcGIS is currently available by request. Use the attached excel spreadsheet to record your comments/suggested edits. Please do not make edits in word.

Please return your review by COB December 14th. Early submission of your review would be greatly appreciated.

Cheers,

rebecca

REVIEW OF “SEA LEVEL AND STORM SURGE PROJECTIONS FOR 118 NATIONAL PARK SERVICE UNITS”

Bob Glahn

This report covers the very difficult subject of trying to forecast relative water level rise in national park units by considering sea level changes, land subsidence or otherwise, and storm surge. In so doing, the MOMs generated with the SLOSH model developed by the Meteorological Development Laboratory (MDL) and the National Hurricane Center (NHC) of the National Weather Service (NWS), NOAA, are used where possible.

I was asked to review this report. I was director of MDL until retirement in 2012. I remain at the NWS as Scientist Emeritus, but I do not, by regulation, speak for the NWS or any governmental agency. The comments are my own alone.

I took a top level approach to the review, but in doing so noted a number of generally minor comments which I include.

Major Comments:

1) SLOSH can be, and has been, run over approximately 32 basins and MOMs created where sufficient past hurricane data exist. Where MOMs are not available, other methods of estimating storm surge were used. There did not seem to be a clear distinction early on that surge of both tropical and extratropical storms was being considered. In fact, the introduction talks specifically of Hurricane Sandy, and concludes with “The aim of this report . . . projections of sea-level rise . . . and 2) how could storm surge generated by hurricanes could also impact these parks.” (The second “could” should be omitted.) This implies to me, only storm surge generated by hurricanes is considered, but the report is not limited to that. It should be made clear in the introduction that storm surge by extratropical storms is also being considered.

2) Under “Methods (p. 3),” it is stated that SLOSH is used, but does not hint that surges where SLOSH is not involved are also estimated.

3) Most maps are rather small and hard to read. The colors used are not optimum for distinguishing the features of importance. The color keys are very small and hard to read. While small figures imbedded in the text make for a nice-looking report, the report would have more utility if the figures were full width or full page, even if they had to be re-oriented by 90 degrees.

4) Because most of the public and emergency management personal dealing with water level use the English rather than the metric system, it would be good to translate the fractional meters of water level to feet in some places. If I were writing the report, it would all be in those units. Feet would be a better attention grabber than fractions of a meter. Metric is the scientific standard, but not the day-to-day language in the US, which I believe the aim of this report should be.
5) P. B3, line 9 – This statement about manmade structures is questionable. MOMs produced by the NWS based on SLOSH output do include dams, levees, canals, etc. to the extent they are known. These are specifically accounted for even to the extent they are sub-grid size.

6) P. 10, Eq. 2 – This equation mixes change with rate of change. I looked up the reference, and it does, also! If the last term is really a rate, say, per year, it would have to be multiplied by the number of years to get change. Perhaps Lentz et al. didn’t really mean rate. But it is JUST INCORRECT to mix units in an equation. This needs to be straightened out.

More Minor Comments:

P. ix – An acknowledgment could be given to organizations whose data you used. For instance, MDL and NHC of the NWS for SLOSH MOMs. But I suppose the reference suffices.

P. ix, line 20– “placement” used on p. 2 is a better definition of flooding than “impoundment.” Impoundment sounds like permanent, but flooding may be temporary, as p. 2 states.

P. 4, line 25 – Replace “choose” with “chose”.

P. 5, line 23 – The “maps” have not been defined at this point. What maps?

P. 5, line 25 – “. . . do not appear” Was this an on-site survey? If not, is this good enough guidance?

p. 6, Fig. 2 – “Blue” is hard to distinguish from ocean.

P. 6, line 27 – The definition of MEOW does not include “overwash.” The “O” stands for “of”. MEOW = Maximum Envelope OF Water.

P. 6, line 27 – MEOWs do not use P-Surge data. MEOWs were defined and generated before P-Surge existed. Replace “P-Surge data” with “SLOSH output”. I doubt you used P-Surge data at all, and it probably has no relevance to the report. P-Surge is a real-time operational NWS product developed by MDL.

P. 7, Fig. 3 – Can’t read detail under black basin extent.

P. 8, line 30 – Awkward sentence. Could use “The bathtub model is the most widely used technique . . .

P. 8, line 30 – “more passive” than what?

P. 8, line 33 – Replace semicolon with comma.

P. 8, line 37 – “Data” is usually used as plural, as it is on p. 9, line 8. Also, p. 9, line 4.
P. 9, lines 22, 23 – P-Surge data not actually used, only MOMs, so what is the relevance?

P. 9, line 36 – “. . . along the Alaska and continental U.S. Pacific coastlines.”

P. 10, Eq. 2 on line 8 – Is it “aE” or “ae”?

p. 10, line 17 – Comma after “records”.

P. 10, line 22 – First use of “you” I have no problem with it, but you could reword.

P. 10, line 26 – Comma after “use”

p. 12, line 10 – Insert “are to be expected”

p. 12, lines 33-35 – Awkward sentence. Also “raster cell” is not generally meaningful to a reader; this relates to how you processed the data.

P. 12, lines 35-37 – Sentence could be omitted or reword.

P. 13, line 4 – I don’t see in Fig. 5 that the northeast and Capital areas are tied.

P. 13, line 7 – Omit “comes”

p. 14, line 21 – Add “8.5” to “(RCP)” for the 0.74 m rise.

P. 16, Fig. 9 – Figure and especially legend are hard to read. Without more identifying features, it may be hard for a reader to locate exactly where the map is located. Again, a full page map would help.

P. 20, line 22 – “is” before “shares” is extraneous.

P. 20, line 24 – Comma after “spectrum”

P. 20, line 26 – “in this region” is unnecessary.

P. 20, line 29 – Commas to set off states and maybe countries, either before or after parentheses. You might want to include the province in Canada, parallel to state in the US.

P. 21, lines 2, 10, 11 – Commas after parentheses to set off states.

P. 21, line 27 – Comma after “Alaska”

P. 22, line 8 – Comma after “Alaska”

P. 22, line 18 – “data show” Data is usually plural.
Page 22 – Has no page number.

Page 23, line 21 – Comma after “level”

Page 24, line 2 – Comma after “Even if such data did exist”  Singular “it” refers to plural “data”

Page 24, line 7 – “as energy” omit “as”

Page 24, line 17 – Comma after “National Seashore”

P. B2, line 30 – Word omitted between “used” and “mapping”? 

P. B2, line 31 – Data “were”

P. B2, lines 31, 32 – Does this mean “. . . were required to have $\leq 18.5$ cm root mean square. . .“? If so, it seems to me “minimum” should be “maximum.” It would be more clear to use “$\leq$“ and omit maximum or minimum.

p. B3, line 2 – Comma after “above”.

P. B3, line 28 – “bath tub” is used as “bathtub” elsewhere (e.g., p. viii, line 19).

Appendix D – It appears page numbered “E1” should be “D1”.

Appendices – Some tables (e.g., D1 and D3) cover more than one page w/o additional headings, but D2 covers multiple pages and has a caption on each page. Suggest you be consistent, and if multiple headings are used, indicate on each after the first that the table is a continuation.

General – There are instances where a period after a sentence is followed by only one space. You could search.

Rebecca,

Attached is my review in MS Word. I would be glad to discuss any items in the review or report you wish. I will likely not be at my desk, so leave a message and I will contact you.

    Hi Bob:

    Thank you for taking the time to speak with me today. Please let me know if
this is a feasible task for you to complete for the National Park Service.

Instructions to Reviewers:

I request your review of a report for the National Park Service entitled “Sea Level and Storm Surge Projections for 118 National Park Service Units”. This report will be released as part of a three year project with the University of Colorado. The report provides sea level and storm surge estimates for 118 coastal park units. These sea level and storm surge estimates were generated by the Intergovernmental Panel on Climate Change (IPCC) and the NOAA. You have been chosen as a reviewer because of your expertise in this matter; you are not expected to review to whether using these datasets was an appropriate choice for this project, but we would like you to assess whether there are any technical errors in how these datasets have been applied and discussed.

Some of the data can be viewed using an online viewer:

The report itself can be downloaded from: https://www.dropbox.com/sh/scfjwntlliasfh0/AAAOMFgzLcS1jL9_vonekjha?dl=0

The online viewer will undergo separate review. ArcGIS is currently available by request. Use the attached excel spreadsheet to record your comments/suggested edits. Please do not make edits in word.

Please return your review by COB December 14th. Early submission of your review would be greatly appreciated.

Thank you for agreeing to review this important dataset for management of our coastal National parks.

Attachments: Reviewer comments_insert last name here.xlsx

NPS Ocean/Coastal/Climate Change Staff based in a WASO or Regional Office:

I request your review of the report entitled “Sea Level and Storm Surge Projections for 118 National Park Service Units”. This report will be released as part of a three year project with the University of Colorado. The report provides sea level and storm surge (SL/SS) projections for 118 coastal park units. These sea level and storm surge projections were generated by the Intergovernmental Panel on Climate Change (IPCC) and the NOAA. A separate, concurrent external peer review will evaluate technical elements in how these datasets have been applied and discussed.

For NPS reviewers, we are interested in any wording changes in pp. vii-25 and "Appendix B: Frequently Asked Question" on pp. B1-4 that may make this material more accessible to more NPS staff.

The report can be downloaded from: https://www.dropbox.com/sh/scfiwmtlliasfh0/AAAOMFgFZLoS1ijL9_vonekjh?dl=0

Use the attached excel spreadsheet to record your comments/suggested edits. Please do not make edits in word. Please return your review by COB December 27th. Early submission of your review would be greatly appreciated. Please cc: maria_caffrey@partner.nps.gov on your response.

Also of interest, yet not covered by this review:

- Some of the SL/SS data can be viewed using an online viewer: The online viewer will undergo separate review. ArcGIS is currently available by request.

Cheers,

rebecca

Comment

This is a very well-written report: your methods and results are easy to follow, and appropriate "side boards" are placed on relevant content for consideration by the reader. The document was clearly crafted with good attention to detail—bravo!

It should be noted that estimates from Aerts et al. are specific to NYC. Also, this sentence is a bit wonky: t sets up an impending contradiction ("While the amount of damage from this storm might seem to be extreme...") then provides damage estimates that reinforce just how extreme it was by comparison.

Reword 2 to read something like "show how storm surge generated by hurricanes..."

Change page number to "ix"

Recommend increasing the size of the figure enough to make the credit line in the lower left corner legible

From "...find out more information..." to "learn"

To keep the subject of both paragraphs cosistent and clear, consider swapping the final phrase of line 3 with the opening phrase of line 4.

Consider shortening statements regarding the implication of sea-ice into a single, succinct paragraph, and move mention of the implications of land-based ice to the very end of the paragraph as a final transitional thought.

And is it proper to say here that the loss of land-based ice contributes to sea-level change?

Unless this table is reference elsewhere (perhaps to demonstrate the increasing rate of rise) it is a poor tool for illustrating additional drivers of SLR, as the language is obtuse. Unless referenced elsewhere, I recommend removing the table and addressing additional drivers in short form in the text.

The question could be asked (and probably should be addressed): why did we filter historic storm intensity using only a 10-mile window (especially given the relative size and large swings in movement observed from past tropical systems?) Coupled with guidance to plan for "one hurricane category higher", this leads to surprisingly conservative recommendations for units in San Juan and peninsular Florida.

"inputted" or "imported", perhaps?

Recommend rewording to: "Changes in various land-based loadings on the continents—such as ice sheets during the last glacial maximum—have been a significant cause of land level change in the U.S.

This line is also a bit confusing: post-glacial isostatic rebound is the result of pressure being removed from the

Currently, it looks like this is being made available only in Appendix A.

Appendix D?

Currently, the sea level change data for regions is rolled out/discussed in this order: 2100, 2030, 2050. For reader clarity, I recommend these results be presented chronologically.

recommend: "...path passed present-day  Boston National..."

recommend: "...indicate the potential height and extend of storm surge generated by...

In reading this, it occurs to me that additional caveats might be necessary (i.e. a nod to the influence of storm direction.) Given SLR projections for the region, complete inundation of EVER might be possible for storms approaching from the west of southwest, but would still be highly unlikely for storms approaching from the east or southeast. This dynamic is also apropos in discussing several other SE region parks.

Change "then" to "the"

I defer to better knowledge, but would suspect that it is more accurate to say: "...discussed how changes in ocean circulation (resulting from warming temperatures and changing salinity) could create...

change "regions" to "region"

change "as energy" to "energy"
Wow, you're so quick. Thanks!

Hi Rebecca

apologies for the delay in getting back to you. I read the brief subsections that you wanted me to double check and everything looks OK, BUT I did not find any mention that the numbers we produced in our 2012 article in terms of storm surge levels are referred to mean high water (MHW) not the zero datum or mean sea level. I may have missed that however, not having read the report in its entirety. I just did a search through the document for "mean high water" and "MHW" and nothing came up. Also, I haven't looked at the data itself that you are making available, I just read the text in the report. Let me know if you wanted me to do something different.

All the best from the AGU circus!

Claudia

PS FYI, Climate Central through its surging seas program made available projections based on different scenarios (for example for the West Coast based on an NRC report that was published after our paper in ERL, by the National Research Council, with Phil Mote at the helm). Also available are slightly updated estimates of storm surges that we worked on at a later time, using observational records that, for some gauges, are longer than the ones used in that paper. Unfortunately at this time I do not have with me the numbers based on that work, but if you are interested I can dig them out next week. Or you can get in touch with Ben Strauss at Climate Central, who has all those numbers.

This report will be released as part of a three year project with the University of Colorado. The report provides sea level and storm surge estimates for 118 coastal park units. These sea level and storm surge estimates were generated by the Intergovernmental Panel on Climate Change (IPCC) and the NOAA. You have been chosen as a reviewer because of your expertise in this matter; you are not expected to review to whether using these datasets was an appropriate choice for this project, but we would like you to assess whether there are any technical errors in how these datasets have been applied and discussed.

Some of the data can be viewed using an online viewer: [b] [5]

The report itself can be downloaded from: https://www.dropbox.com/sh/scfjwntfljasffh0/AAAOMFgFZLoS1jL9_vonekJha?dl=0

The online viewer will undergo separate review. ArcGIS is currently available by request. Use the attached excel spreadsheet to record your comments/suggested edits. Please do not make edits in word.

Please return your review by COB December 14th. Early submission of your review would be greatly appreciated.

60 Request review by Dec 21 for NPS SL.SS Report.pdf
Hi John:

I realize I did not hear back from you about this request sent 1 month ago. Steve Nerem has been an NPS advisor to this project and recommended you as a reviewer of the application of the IPCC Sea level model to this product for coastal units of the National Park Service.

Can you provide this review by 12/21? We have extended some reviewer deadlines until that date.

We need your review to demonstrate a robust external peer review and thank you in advance for your time.

Cheers,
rebecca

Hi Rebecca,

Thanks for getting back to me. I have been on travel for all but 4 days since your original email and alas am off again this morning to take my family skiing for a long weekend. Given this I don’t see a window of opportunity to contribute to this review. Please keep me in mind for future work however as I would relish the opportunity to contribute to the National Park Service’s mission.

Sincerely,
John

Hi Rebecca,

If you send Word version, I can suggest language, but here are some suggestions:

Suggested changes in italics:
The NPS published a Coastal Adaptation Strategies Handbook and a companion Case Studies Report for coastal area park response to effects associated with storms and sea level rise. add link

Suggested additional bullet, or to add to a vulnerability assessment one:
The University of Rhode Island Coastal Resources Center is developing vulnerability assessment methods integrating across natural resources, cultural resources and facilities, piloting it at Colonial National Historical Park.

This is a stylistic thing, but for the SLR& storm change, I prefer to start out Background with SLR info (rather than 1.5 sentences before you get to it). Would be more user friendly to have title/heading of Category 2 hurricane instead of the wind speed. I'm assuming Maria is suggesting updates to reflect publication details from the will be completed in 2016.

Rebecca and Maria,

It is that time of year again when we like to update our program briefs. I really need
some help from you two! The coastal adaptation and sea level change briefs are attached. If you wouldn't mind just perusing them and offering some changes for 2016, I would really appreciate it. There is no need to rewrite the entire brief, we would just like to update with current information. I hope you have a great holiday!

Hi Rebecca

apologies for the delay in getting back to you. I read the brief subsections that you wanted me to double check and everything looks OK, BUT I did not find any mention that the numbers we produced in our 2012 article in terms of storm surge levels are referred to mean high water (MHW) not the zero datum or mean sea level. I may have missed that however, not having read the report in its entirety. I just did a search through the document for "mean high water" and "MHW" and nothing came up. Also, I haven't looked at the data itself that you are making available, I just read the text in the report. Let me know if you wanted me to do something different.

All the best from the AGU circus!

Claudia
PS FYI, Climate Central through its surging seas program made available projections based on different scenarios (for example for the West Coast based on an NRC report that was published after our paper in ERL, by the National Research Council, with Phil Mote at the helm). Also available are slightly updated estimates of storm surges that we worked on at a later time, using observational records that, for some gauges, are longer than the ones used in that paper. Unfortunately at this time I do not have with me the numbers based on that work, but if you are interested I can dig them out next week. Or you can get in touch with Ben Strauss at Climate Central, who has all those numbers.

Since you have chosen the IPCC projections over the semi-empirical approach, you should probably briefly mention that other agencies have put forward a range of planning curves for coastal managers including semi-empirical-based curves which rise more rapidly. I see you that you have a paragraph about this in the Discussion section (page 23 line 1), but a sentence or two at the beginning would help.

Substitute ‘for 2015’ with ‘using all available data including 2015’

Cross out ‘relative to global mean sea level’. A trend is not relative to any level.

Substitute ‘ice wholly contained within water and not supported by land’ with ‘ice wholly supported by water’

This paragraph is another place to note that the semi-empirical approach can result in projected levels over twice as high as the IPCC’s process-based approach.

This is an important point. Most of southern Alaska is rising rapidly with spatially and temporally variable rates. Therefore, the present-day vertical land motion must be measured directly at the parks in order to make any

HI Chris:

Thank you for your time to consider this review. Please let me know if this is a feasible task for you to complete for the National Park Service.

Instructions to Reviewers:

I request your review of a report for the National Park Service entitled “Sea Level and Storm Surge Projections for 118 National Park Service Units”. This report will be released as part of a three year project with the University of Colorado. The report provides sea level and storm surge estimates for 118 coastal park units. These sea level and storm surge estimates were generated by the Intergovernmental Panel on Climate Change (IPCC) and the NOAA. You have been chosen as a reviewer because of your expertise in this matter; you are not expected to review to whether using these datasets was an appropriate choice for this project, but we would like you to assess whether there are any technical errors in how these datasets have been applied and discussed.

Some of the data can be viewed using an online viewer:

The report itself can be downloaded from: https://www.dropbox.com/sh/scf

The online viewer will undergo separate review. ArcGIS is currently available by request. Use the attached excel spreadsheet to record your comments/suggested edits. Please do not make edits in word.

Please return your review by COB December 14th. Early submission of your review would be greatly appreciated.

Sounds good. Looks like John just can't do it.

I could ask Billy Sweet to look it over, but he was someone who had applied for the sea level position in OCRB. I don't know if that would be an issue (probably not because Billy seems very professional based on the few emails we've exchanged).

Hi Cat,

I wanted to share with you the sea level/storm surge project report that Rebecca and I have been working on. It's a rather large file that is too big to attach to an email, so I've included a link to it:

https://drive.google.com/open?id=oBxhhWNH7lJJwU2hXWUJQTUZWbTQ

We have spent a lot of time putting the report through review, but I think it's almost ready to go public. We are aiming to release it by the end of this month. I really appreciate all of the support that I've received from CCRP on this project and I was wondering if you would like to be a co-author on it?

Congratulations on the promotion too. That's excellent news.

Cheers,

Did you ask or consider Amanda as an author. I think she had far more input than Cat. Still think it is good to keep Cat- more ownership we can show in NPS the better.

Hi Cat,

I'm not sure if you have gotten around to reading the report yet. I need to send it out ASAP (within the next day or two). I'm assuming that you're ok to be kept on as an author on this. Can you confirm that you want to be a co-author?

Cheers,

In a CCRP call this afternoon, I told both amanda & cat that you would follow- up with them on some final details that need to be confirmed before the report is published. We need to check with Larry on 508 compliance for the report, too.

I have one more report review to complete by COB and will let you know when I am done. Tomorrow AM ~ 9:30 am should be OK if you want to schedule a time.

Hi Maria -- I'm glad that Rebecca sent a "nudge" to me through Larry yesterday -- things definitely fall below my radar, particularly lately with several short-turnaround transition tasks that are coming in.

I would like to be a co-author on the report, although if you feel I haven't contributed enough, it won't insult me if you decide not to include me!

Ray is organizing a cross-directorate meeting next week to talk about our profile and messaging around our work. I'll know more after that about how we can move forward with this report.

In the meantime, are you still open to some comments on the document?

81  Peer review manager update_ Caffrey Sea level_s....pdf
Hi John:

Cat is making her revisions to the final version of the sea level/storm surge projections report that now addresses internal and external peer review comments. She anticipated providing her comments to us by Friday.

I'll send the draft Manuscript Submittal Form to you approx early next week for review and comment along with 1) the final version of the paper and 2) the spreadsheet we have for tracking comments and responses to comments.

Thanks.

-rebecca

Rebecca,

I have attached the manuscript submittal form for the sea level/storm surge report. I've filled it out as much as I can. We will have to add the report numbers later along with a date for the program managers approval. Cat is still reviewing the document, but she should get it back to us this week. I haven't attached the final report because I will need to include Cat's edits once I get them back, but I thought it would be good to get the manuscript submittal forms ready. Hopefully this should all be ready for the next step in a week or so.

I have the majority of the reviewer comments in spreadsheets that I could upload onto the drive for John to review if he would like me to. I've made notes next to each comment explaining how we tackled each comment. I have a couple reviews that are in a PDF format because the reviewer preferred to email their comments. I have a document that explains my replies to each of Bob Glahn's lengthy comments, but I don't have anything for the smaller emailed comments from Claudia Tebaldi and Steve Nerem.

Cheers,

3. *Report Series* - select series that is appropriate for the manuscript

☐ **Natural Resource Data Series (NRDS)** (proceed to sections 2 and 4 below)

   Intended for the timely release of basic data sets and routine data summaries that are based on data collection and data management methods documented in established, peer-reviewed protocols. While QA procedures have been completed to assure the accuracy of raw data values, analysis or interpretation of the data has not been completed and should not be included in NRDS manuscripts. (see NRDS guidance and tips)

☒ **Natural Resource Report (NRR) series** (proceed to sections 3 and 4 below)

   Intended for comprehensive information and analysis about natural resources and related topics concerning lands managed by NPS. NRR manuscripts may include quantitative data that are accompanied by analysis and/or interpretation; procedural documents such as protocols and standard operating procedures; planning or policy information; and/or resource management information.

   **Note:** If the manuscript meets criteria for 'Highly Influential Scientific or Scholarly Information' as defined by the OMB Peer Review Bulletin (i.e., provides the sole or major component of information used in decision-making; or, by itself, leads to a change in the direction of decision-making or to a decision that creates a clear and substantial impact on important public policies or private sector decisions), publication should not occur in the NRR.

**SECTION 2. NRDS Manuscript**

This section applies only if you are publishing in the **Natural Resource Data Series**.

No peer review is required for these reports; however, program management review is recommended.

  * Citation or link (preferred) to protocol associated with report:

    n/a

**SECTION 3. NRR Manuscript**

This section applies only if you are publishing in the **Natural Resource Report series**. This series requires peer review.

This section should be completed by the program manager who is assuming responsibility for the content of the manuscript. **Note:** Authors can never hold the role of Program Manager or Peer Review Manager for a manuscript.

Current NPS peer review guidance requires that NPS scientific and scholarly activities comply with OMB Final Information Quality Bulletin for Peer Review (2004; 70 FR 2664-2677), and NPS Director’s Order (DO) #11B: Ensuring Quality of Information Disseminated by the National Park Service.

Peer review of the manuscript must comply with the NPS Interim Guidance on Peer Review. If the manuscript is submitted by or on behalf of the Inventory and Monitoring Division, it must also adhere to IMD-specific guidance...
3.1. Peer Review Manager

The peer review manager oversees the peer review process of this report, and assumes responsibility for the manuscript fully meeting NPS peer review guidance. Manuscripts submitted by the Inventory and Monitoring Division must also meet the latest version of the IMD Peer Review Policy (NPS-only).

The peer review manager recommends, to the program manager, the technical acceptance of the manuscript in a written record documenting the process. The peer review manager is also responsible for maintaining all records associated with the peer review process, including correspondence, comments, and responses.

* Peer Review Manager Name: John Gross

* Title: Climate Change Ecologist

3.2. Peer Review Summary

Briefly describe the major review comments addressed, and areas of the report that were revised during the peer review conducted by the Peer Review Manager.

Peer review was carried out using both internal and external reviewers. Reviewers were selected based on their expertise in one or more fields relating to coastal climate change, sea level change, or storm surge. The following people reviewed the document: Amanda Babson (NPS), Ann Gallagher (NPS), Larry Perez (NPS), Steve Nerem (University of Colorado), Bob Glahn (emeritus, NOAA), Doug Marcy (NOAA), Chris Zarvas (NOAA), Rob Thieler (USGS), and Claudia Tebaldi (Climate Central). All peer review comments have been compiled in either spreadsheets as PDFs. Descriptions of how each comment was addressed is included in the spreadsheets. Comments covered the entire report. Peer reviewers were not supplied the GIS data referenced in this report. The GIS data will undergo a separate review.

Provide confirmation that peer and management review comments have been adequately incorporated into the final manuscript.

The report authors were responsible for the incorporation of peer and management comments into the final manuscript. These edits were reviewed by peer review manager John Gross to ensure that their edits adequately addressed the peer and management comments.

☐ Yes ☒ No Does the manuscript include any sensitive or commercially valuable information that may potentially jeopardize a park resource or that might justify a management review by a qualified individual? If yes, please explain

Click here to enter text.
☐ Yes ☒ No

Is there policy-sensitive material in the manuscript that might justify a management review by an appropriate reviewer who can verify consistency with or clear and appropriate relation to NPS policy? A management review should be conducted if any material might not be consistent with NPS policy. If one of the reviewers is qualified to conduct such a review and has already done so, please explain.

Click here to enter text.
SECTION 4. Approval and Publication

4.1 Program Manager Approval

The NPS program manager has final authority to approve publication of the manuscript, and assumes responsibility for this report’s adherence to scientific integrity, administrative and policy standards.

* Program Manager Name: Cat Hawkins-Hoffman

* Title: Chief, Climate Change Response Program

‘ Date Approved for Publication: Click here to enter text.

4.2. Report Numbers and Data Store Record Owners

Provide the name and email address of additional NPS employees who should receive the final publication review notice from the series manager, and who should review the associated NPS Data Store record.

Name: Click here to enter text.

Email: Click here to enter text.

Name: Click here to enter text.

About This Template

This template is intended for use by authors who are preparing a final draft of a report that will be sent to a dedicated NPS layout expert (who will format the report to meet NRR Full Template standards). *Do not use this template if you do not have access to such an expert and intend to submit the report for publication yourself.* Instead, prepare your report using the NRR Full Template.

Not sure how to do something as instructed in the template? Click on the hyperlinks provided. **Note:** Most links in this document will only work if all five files in the NRR_Template_4.0.zip file are unzipped into the same drive folder.

How to Use This Template

1) Prepare your report using this template and MS Word 2013 or later.

2) Provide the title, authors, and cover image(s) on the following 3-4 pages.

3) Prepare your report using the basic template examples that begin on the **First Order Heading Example** chapter.

   a) Use the MS Word Styles built into this template (style names that begin with “nrps ”) for all text elements throughout the report (Rules/Guidance – see all text elements built into this template for working examples, and the See the NRR Full Template for additional examples).

      i) To see the Styles, go to the Home tab, find the tile that says “Styles,” and click on the little arrow in the lower right-hand corner.

      ii) All headings should be applied in a logical order (styles nrps Heading 1–6; first-order headings come first, followed by second-order headings, etc.).

   b) All pages must be in single-column layout.

   c) Always include an abstract or executive summary (see full template Abstract or Executive Summary).

   d) Always include a brief introduction or similar section (see full template Introduction).

   e) Make sure that the written content of your entire report is characterized by the following.

      i) Correct and consistent grammar, punctuation, capitalization, and spelling

      ii) Straightforward, concise, and natural wording

      iii) Defined acronyms and abbreviations (at first usage)

      iv) Findings were clearly and coherently presented

   f) All graphics (photographs, maps, charts, etc.) should (Rules/Guidance)

      i) If the graphics show data results or analysis, facts, or contextual information (maps, charts, etc.), they should be added to the report as figures and referenced in the text section immediately before the figure (see full template Figure 1, Figure 2, Figure 3, Figure 4, and Figure 5).

      ii) If they are purely decorative graphics (i.e., photos and images that do not show data results or analysis, facts, or contextual information), they should not be treated as figures or referenced in the text in most cases (see full template Example 1 and Example 2).

      iii) Be added directly to the page (not still housed in an external file).

      iv) Stay within the page margins (Rules/Guidance).
v) Be in-line with text (no text wrapping around the graphic or the caption).
vi) Be easy for the reader to discern and all major text attributes (legends, major feature labels, etc.) must be legible.

vii) Be saved as separate graphics files whenever possible and made available upon request by the NRPM support staff.

(1) Prior to importing them into MS Word, photos and like images (.jpg, .png, etc.) should be saved as separate files that are close to the same dimensions displayed on the MS Word page (inches wide and tall) at 300-600 ppi/dpi (pixels per inch / dots per inch).

(2) MS Office charts or Draw elements (saved in stand-alone MS Word or Excel files; charts should be the same size as will be used on the actual page).

(3) All vector-based graphics (should be saved to Adobe Illustrator (.ai) or Scalable Vector Graphics formats (.svg - supported by most GIS, statistics, and plot generating software)).

h) Tables should

(Rules/Guidance – see full template Table 1, Table 2, Table 3, Table 4, and Table 5)
i) Always be MS Word tables added directly to the page (not pictures of tables, or tables still housed in external files, or other treatments that only "look like" tables).

ii) Always have multiple columns and rows. Single-column content should be added as lists.

iii) Stay within the page margins (Rules/Guidance).

iv) Not be split into multiple tables when the table spans multiple pages (this will be done for you later).

v) Have consistent layout schemes (borders, backgrounds, table notes, etc.) throughout all chapters.

vi) Not be nested inside of other tables or text boxes.

vii) Not have a single-column (please use bulleted or numbered lists instead).

2) Authors should use this copy for peer review and editing (review of all content and language).

3) When you have a final draft that is ready for final layout and editing, send the report to a dedicated NPS layout expert who will reformat each page of the report to meet full template standards.

4) Work with the NPS peer review manager and the NRR layout editor to make sure that the final report meets NRPM peer review standards and to publish the report.

After completing the tables shown above, begin your report on the following page. If desired, don’t forget to include an Acknowledgements section and an Executive Summary. Please contact your layout person or Fagan Johnson with any questions about this template or the publications process.

First Order Heading Example (Style: `nrps Heading 1`)

Use the MS Word Styles built into this template (style names that begin with “nrps”) for all text elements throughout the report (Style `nrps Normal` - Rules/Guidance for using Styles - see template text elements for working examples - see the NRR Full Template for additional examples).

Second Order Heading Example (Style: `nrps Heading 2`)

All headings should be applied in a logical order (styles `nrps Heading 1–6`; first-order headings come first, followed by second-order headings, etc.).

Third Order Heading Example (Style: `nrps Heading 3`)

Lorem ipsum aliquet tincidunt bibendum ultrices mi himenaeos, auctor elit justo consequat litora tempor, faucibus quis elementum platea quisque tristique sapien consectetur dictumst eu porta diam sodales platea.

Fourth Order Heading Example (Style: `nrps Heading 4`)

Platea lacinia elementum lacus feugiat scelerisque cursus commodo, cras dui congue quisque blandit elit dolor tortor.

Fifth Order Heading Example (Style: `nrps Heading 5`)

Interdum auctor tempor aenean duis bibendum ipsum dapibus primis suscipit, est dictumst dui adipiscing aliquam adipiscing nec mi vitae (Table 1).

Rebecca,

I have attached the manuscript submittal form for the sea level/storm surge report. I've filled it out as much as I can. We will have to add the report numbers later along with a date for the program managers approval. Cat is still reviewing the document, but she should get it back to us this week. I haven't attached the final report because I will need to include Cat's edits once I get them back, but I thought it would be good to get the manuscript submittal forms ready. Hopefully this should all be ready for the next step in a week or so.

I have the majority of the reviewer comments in spreadsheets that I could upload onto the drive for John to review if he would like me to. I've made notes next to each comment explaining how we tackled each comment. I have a couple reviews that are in a PDF format because the reviewer preferred to email their comments. I have a document that explains my replies to each of Bob Glahn's lengthy comments, but I don't have anything for the smaller emailed comments from Claudia Tebaldi and Steve Nerem.

Cheers,

Maria Caffrey, PhD

Bill & Jen,

In an effort to help consolidate our reporting, I'm sending you both these submissions from CCRP for your respective purposes. Please let me know if this new method of reporting will work for you going forward.

Many Thanks,

Larry

P.S. I hope to one day work at Mordor National Park, Jen ;)

3-Week Outlook
On February 14-15, Colonial National Park, Northeast Region, and the Climate Change Response Program will host the final in the 3-part workshop series to assess vulnerability across natural resources, cultural resources, and facilities. The effort is being coordinated in partnership with the University of Rhode Island. (Contact: Amanda Babson, 401-874-6015)

Beginning February 29, the Climate Change Response Program will host Interpreting Climate Change, a three-day virtual workshop for communications personnel on interpreting climate change with park audiences. The curriculum familiarizes attendees with audience segmentation trends, best practices, and potential program themes. (Contact: Larry Perez, 970-267-2136)

Sometime early March, the Climate Change Response Program and Geological Resources Division will release a peer-reviewed report on projections of sea level and storm surge for 118 coastal parks. (Contact: Rebecca Beavers, 303-987-6945)

Here is the sea level rise report, with edits and comments that I just sent back to Maria Caffrey. The report has been peer reviewed for methodology and conclusions; my edits are largely for clarity.

Although it's possible, I'm not sure that the final version will be available in 3 weeks, so this could be an even earlier "heads up."

my comments. I didn't get into the gory details of the numbers etc. in the Appendices but rather looked at it from a more general sense with overarching method comments.

Hope this helps. Let me know if you all have questions.

Doug

On Tue, Nov 15, 2016 at 2:27 PM, Beavers, Rebecca <rebecca_beavers@nps.gov> wrote:

Hi Doug:

Thank you for your time to consider this review. Please let me know if this is a feasible task for you to complete for the National Park Service. we need one reviewer with experience with applications of SLOSH Results.

Instructions to Reviewers:

I request your review of a report for the National Park Service entitled “Sea Level and Storm Surge Projections for 118 National Park Service Units”. This report will be released as part of a three year project with the University of Colorado. The report provides sea level and storm surge estimates for 118 coastal park units. These sea level and storm surge estimates were generated by the Intergovernmental Panel on Climate Change (IPCC) and the NOAA. You have been chosen as a reviewer because of your expertise in this matter; you are not expected to review to whether using these datasets was an appropriate choice for this project, but we would like you to assess whether there are any technical errors in how these datasets have been applied and discussed.

Some of the data can be viewed using an online viewer: (b) (5)
The report itself can be downloaded from: https://www.dropbox.com/sh/scfjwnltliasdfh0/AAAOMFgFZLoS1jL9_vonekJha?dl=0

The online viewer will undergo separate review. ArcGIS is currently available by request. Use the attached excel spreadsheet to record your comments/suggested edits. Please do not make edits in word.

Please return your review by COB December 14th. Early submission of your review would be greatly appreciated.

Cheers,

rebecca

I have attached some slides. The first slide is a summary slide. I've also included a number of other slides that either just show maps or a summary of the methods. I wasn't sure which direction you would like to take the second slide in, so I've given you a bunch of options to choose from. Feel free to delete all the extra stuff. I think the first slide is fine by itself.

Sea Level/Storm Surge Project

- Project is lead by Dr. Maria Caffrey
- The project covers 118 coastal units
- The report will be released in the coming months

More information at:
https://www.nps.gov/subjects/climatechange/sealevelchange.htm

October 2016 Caffrey webinar [NPS internal site]:
https://tinyurl.com/caffreywebinar
Sea Level/Storm Surge Project

- Sea level projections use the source model for the latest (AR5) IPCC report
- We used projections directly from the report for 2050 and 2100
- We also downscaled sea level rise for 2030
- Used NOAA SLOSH model to estimate storm surge

Key strengths of this approach:
- Uses the latest CMIP5 data (coupled models that use the new representative concentration pathways)
- Widely respected data sources
- Nationwide coverage for sea level rise
- Maximum coverage for storm surge
Storm Surge

Winds 157+ MPH - Mean Tide
Sea Level Rise By Region

Projected future sea level by region for 2100 under RCP8.5.

Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each average. Blue bars mark the full range of sea level estimates for each region. These averages do not include the impact of land movement.
Comparing Parks

- Highest sea level rise by 2100 (RCP8.5) = Wright Brothers National Memorial/Cape Hatteras National Seashore

- Lowest sea level rise by 2100 (RCP8.5) = Glacier Bay National Park and Preserve and Klondike Gold Rush National Historical Park

- Strongest (by pressure) historical storm = Everglades National Park
Thank you! Any news from greeley?

I have added the report to this folder: N:\GRD\Programs\Climate Change - Beavers & Brunner\Caffrey Sea Level Projections\Final report\Manuscript submittal form

You might want to give it another read before sending on. I changed the title to "Sea level rise and storm surge projections for the National Park Service." I'm open to other title suggestions for the title. I just shortened it a little more to get around Cat's suggestion that it be "Sea level rise and storm surge projections for 118 and 79 National Park Service units (respectively)."

Northeast Region Climate Change Toolkit

Find Your Park: Women's Rights National Historical Park tells the story of the first Women's Rights Convention held in Seneca Falls, NY on July 19-20, 1848. It is a story of struggles for civil rights, human rights, and equality, global struggles that continue today.
Review of Caffrey et al. *Sea Level Rise and Storm Surge Projections for the National Park Service*

- p ix line 9 - delete "the" in the sentence "We would also like to thank the Susan..."
- p 1 introduction - "Melilo" should be "Melillo" ?
- p 1 introduction - it is not clear what 1/398, 1/1570, 1/100 means. I'd suggest writing it out in words at least in the first instance (1/398).
- p 2 first paragraph- add "regions" to end of sentence, to read "...Pacific West, and Alaska regions."
- p 2 first paragraph- add "to" so that it reads "...are vulnerable to the effects of..."
- p 2 second paragraph- when referring to a word as the word itself, put it in quotations marks:
  - 'we use the term "flooding" to describe...'
  - similarly, "..."Inundation" is used to refer to...'
  - similarly, for consistency in the last paragraph, put "sea level change" in quotation marks instead of italics in the sentence 'For this reason, we use the term "sea level change" as it...'
- p 4 methods – Suggest adding a comma to first sentence to read “...project, initiated in 2013,...”
- p4 methods item 3- change “impact” to “impacts”
- p 4 header “Sea level Rise Data” capitalize ‘level’
- p 5 remove ‘to’ in the sentence “AOGCMs to simulate the processes...”
- p 6- Move the explanation of what a “simple bathtub model” is from p 9 to here.
- P 7 fig 2 caption- add “Island” to “Assateague National Seashore”
- P 7 revise the verb in the sentence “The NOAA SLOSH model is comprised of the...” to read either “model is composed of the following” or “model comprises the following”
- p 7- Is it safe to assume that readers will know what probabilistic, deterministic, and composite approaches are? If not consider adding a brief explanation of their differences.
- P 9 first paragraph – change “Alaskan” to “Alaska” for consistency with “Guam, and American Samoa park units”
- Ensure verb consistency with the plural “data” throughout document
  - P 10 first paragraph “... data that either meets or exceeds...”
  - P 10 first paragraph “This is discussed in more detail in the metadata that accompanies each map.”
  - P 10 first paragraph “USGS data was used for areas, such as Alaska...”
  - P 11 “All GIS data from this project is available...”
- P 11 missing the word “the” in the sentence “...given that many of park units are some distance from...”
- P 12 add a period to the end of the second sentence “...in Appendix D Following...”
- P 15 second paragraph capitalize “region” in “Alaska region”
- P 17 second paragraph: “the” should be lowercase in the sentence “For example, The Eugene Island...”
• P 17 second paragraph: revise “sea level” to “change in sea level” in both mentions here: “…we can see that relative sea level is more than double the projected sea level using the IPCC estimates alone.”
• P 24- “Glacier Bay Preserve” should be “Glacier Bay National Park and Preserve”
• P 27- first paragraph- add “Island” to “Assateague National Seashore”
• Appendix D – please repeat column headers on every page.
thank you.

Find Your Park: Women's Rights National Historical Park tells the story of the first Women's Rights Convention held in Seneca Falls, NY on July 19-20, 1848. It is a story of struggles for civil rights, human rights, and equality, global struggles that continue today.
Amanda, Courtney & I flagged many typos in what is a copy edit phase. Some phrasing and content still stood out as needing revision, etc.

Document is attached and available as a Google Doc. https://drive.google.com/open?id=1LG4oyWW5CU4Pvto1EY1DPxeFLu6CqpmGKKCAEAYA0

Let's discuss on Monday. Have a great weekend.

Review of Caffrey et al. *Sea Level Rise and Storm Surge Projections for the National Park Service*

- p ii change title in citation
- p iii remove additional space prior to Frequently Used Terms, p 2
- p iii Capitalize Level in Sea Level Rise Data, p 4
- p iv Figure 1. Change second “based on” to “for” or other similar term
- p iv Captions for Fig 4,5,6, 3rd or 4th line, delete one term in “of from”: should be worded similar to Figure 7.
- p iv fig 6. line 2, delete extra space before 1st period. “scenario).”
- p v. Table D3 replace was with “were”. Data are plural.
- p vi Photo 2. delete “th” after December 5.
- p vii line 17-18: delete “, and show how storm surge could propagate in the future” as you no longer do this.
- p. vii, line 20 delete comma after units.(unless you really want to keep it to make the reader pause.)
- p. ix, line 2, replace comma with and
- p ix, lines 5 and 6 add Rebecca Beavers as a member of both teams.
- p ix line 9 - delete “the” in the sentence "We would also like to thank the Susan..."
- p 1 introduction, para 1. - "Melilo" should be "Melillo" ?
- p 1 introduction, para 2, sentence 1 - Used revised sentence from abstract wiht subset (79).
- p 1 introduction, para 2, line 7 - After “this report is to” replace “,” with “:.”
- p 1 introduction, para 3 - it is not clear what 1/398, 1/1570, 1/100 means. I'd suggest writing it out in words at least in the first instance (1/398).
- p 2 first paragraph- add "regions" to end of sentence, to read "...Pacific West, and Alaska regions."
- p 2 first paragraph- add "to" so that it reads "...are vulnerable to the effects of..."
- p 2 second paragraph- when referring to a word as the word itself, put it in quotations marks:
  - ‘we use the term "flooding" to describe...'
  - similarly, '..."Inundation" is used to refer to...'
  - similarly, for consistency in the last paragraph, put "sea level change" in quotation marks instead of italics in the sentence 'For this reason, we use the term "sea level change" as it...'
- p 4 methods – Suggest adding a comma to first sentence to read “...project, initiated in 2013,...”
- p4 methods item 3- change “impact” to “impacts”
- p4 methods, last paragraph is awkward in its placement as a paragraph hanging out there. I would add a shorter version of the text under 3.
- p 4 header “Sea level Rise Data” capitalize ‘level’
- p4 Sea Level Rise data, sentence 1, replace :“results from” to “is caused by”
- p 4 delete s from Lakes (SLOSH is Lake singular)
- p 5 remove ‘to’ in the sentence “AOGCMs to simulate the processes...”
- p 6- Move the explanation of what a “simple bathtub model” is from p 9 to here.
- P 7 fig 2 caption- add “Island” to “Assateague National Seashore”
- P 7 revise the verb in the sentence “The NOAA SLOSH model is comprised of the…” to read either “model is composed of the following” or “model comprises the following”
- p 7- Is it safe to assume that readers will know what probabilistic, deterministic, and composite approaches are? If not consider adding a brief explanation of their differences.
- P 9 first paragraph – change “Alaskan” to “Alaska” for consistency with “Guam, and American Samoa park units”
- p 9 delete “to” in “near to a tide gauge”
- p 9 be consistent in “tidal gauge” vs “tide gauge”. I suggest using using “tide gauge”
- p 9 2nd to last line, extra space between “in” and “methods”
- p 10 first line, extra space before “horizontal”
- Ensure verb consistency with the plural “data” throughout document
  - P 10 first paragraph “… data that either meets(meet) or exceeds(exceed)…”
  - P 10 first paragraph “This is discussed in more detail in the metadata that accompanies (y) each map.”
  - P 10 first paragraph “USGS data was(were) used for areas, such as Alaska…”
  - P 11 “All GIS data from this project is(are) available…”
- P 11 missing the word “the” in the sentence “…given that many of park units are some distance from…”
- p 12 1st link page does not exist, 2nd link, I got an error
- p 13 2nd line, extra space before “Appendix”, missing period after “Appendix”
- p 13 last line, delete “above waterline”, this is not a meaningful datum and is unnecessary
- p 13-14 figure caption revision. see comment on p iv
- P 15 second paragraph capitalize “region” in “Alaska region”
- P 15 last sentence in 2nd to last paragraph, I suggest adding the clarifying phrase in italics to “units of this highest rise grouping that contain coastline with their boundaries.” or something to that effect. After Fort McHenry, add National Monument and Historic Shrine.
- p. 15, last sentence. add m in final numbers. -0.54 m)
- P 17 second paragraph: “the” should be lowercase in the sentence “For example, The Eugene Island…”
- P 17 second paragraph: revise “sea level” to “change in sea level” in both mentions here: “…we can see that relative sea level is more than double the projected sea level using the IPCC estimates alone.”
- p. 17, para 3. I don’t know that discussion of the highest rates of SLR at WRBR is worthwhile. We do not and will not manage that shoreline. I suggest eliminating this paragraph.
- p. 19-20 This is probably past the time for this suggestion, but the Harpers Ferry paragraph highlights that this park does not belong in the analysis. I suggest deleting or rewording to say that Harpers Ferry should not have been included in the study because it is not subject to sea level rise, it is way upstream on a non-tidal river. Or Rebecca Suggests eliminating this information from the paper. These types of topics really detract from the overall results. I suggesting cutting Harpers Ferry from the overall study, tables, etc.
- p 20 2nd paragraph, suggest changing “would” to “could have widespread impacts.”
● p 20 last sentence, I suggest deleting because outside of scope of study
● P 24- “Glacier Bay Preserve” should be “Glacier Bay National Park and Preserve”
● p 26, Sallenger et al paragraph, again this is probably past time for this suggestion, but it is logically flawed/inconsistent with what is in paper. At a minimum, delete “, combined with storm surges”. Issues: 1) Sallenger does not combine with storm surge, 2) Sallenger is observations, but “could create” makes it sound like projections, 3) you’re comparing to your flooded projections (so storm surge) not inundated
● P 27- first paragraph- add “Island” to “Assateague National Seashore”
● p 27 extra space between “in” and “coastal”
● p 27 Aerts reference. Replace comma after New York City with a period.
● p. 28 Duff reference. Replace comma after Record with a period.
● p. 28 Glahn. eliminate comma after Digest.
● p. 29 Lin Write out PNAS as “Proceedings...” see Lambeck.
● p. 30 Melillo reference. add period after C in T.C. Richmond.
● p. 30 Rahmstorf, second ref. Eliminate comma after Change and “no.”
● p. 31 Schmid. use quotes around paper title.
● p. 31 Tollefson. eliminate comma after Nature.
● p. B-1 4th question, Rephrase question to read “use data from Tebaldi” or other phraseing to eliminae 2nd “use/used”
● p. B-1 5th question. insert and before Wrangell
● p. B-2 Saffir-Simpson question: insert “into the northern latitudes of” after “sustain itslef into”
● p B-2 , Question What are the effects of NAVD88 on projections for some parks? is confusing and needs work. The sentence “It uses a fixed value for the height of the sea level.” is inconsistent with my understanding of NAVD88 and our uses of datums in general.
● p B-3 1st answer needs some work: “For example, El Niño and La Niña years will impact sea level. “ needs to connect the dots between impacts to sea level and differences in storm surge.
● p B-3, I suggest adding “storm surge barriers” to “such as levees and dams”
● p B-3 This is another one that it may be past time for suggestion, but I suggest moving the sentence “Permanent inundation will change the way waves propagate within a basin in the future. “ to the beginning of the answer and rewriting it to “Higher sea level and permanent inundation will change the way waves propagate within a basin in the future”. and I guess the following sentences should go forward with that one too.
● p. B-4 Why are only adverse impacts included in this answer?
● Appendix D – please repeat column headers on every page.
Hi Rebecca and Maria,

Thank you for sending the final draft of the sea level rise report. I was grateful that Maria invited me to be a co-author. I had only seen the draft last year before it went out for review and before Maria’s invitation.

I recognize that Rebecca wants to wrap up the process quickly now. Yet, since I’m listed as a co-author, I needed to go through the draft in detail. You will receive a second e-mail with a URL link to the document on the National Park Service ftp site with my recommended edits tracked in Word. I have sought to only make edits for scientific clarity and accuracy. You will find explanatory comments for many of the edits.

I hope that you recognize the value of the recommended edits and that any delay will make the report scientifically stronger. I can talk on the telephone if that would be helpful.

Thanks for all of your work.

Best regards,

Patrick

I have added the report to this folder: N:\GRD\Programs\Climate Change - Beavers & Brunner\Caffrey Sea Level Projections\Final report\Manuscript submittal form

You might want to give it another read before sending on. I changed the title to "Sea level rise and storm surge projections for the National Park Service." I'm open to other title suggestions for the title. I just shortened it a little more to get around Cat's suggestion that it be "Sea level rise and storm surge projections for 118 and 79 National Park Service units (respectively)."

On Tue, Mar 21, 2017 at 8:03 AM, Smith, Tim <tim.smith@nps.gov> wrote:

A. The North American Vertical Datum of 1988 (NAVD88) is the most commonly used vertical datum for North America. It is what most people refer to as the "elevation" of a location. It uses a fixed value located at Rimouski, Canada for the height of North America's mean sea level (MSL). While this is a popular datum for mapping, it has the limitation of being based on the observed mean sea level at a single location. As you move farther away from this datum point you can expect the local observed mean sea level to differ from the MSL height at Rimouski. For locations such as California, this can result in a significant difference between observed local mean sea level and the local NAVD88 height. Your natural resource or GIS specialist may have further information about your specific location. Alternatively, you can look up the differences in your region by checking the datum information for your nearest tide gauge station at the NOAA website: https://tidesandcurrents.noaa.gov/stations.html?type=Datum. Keep in mind that MSL (Mean Sea Level) is not the same as the NAVD88 height. If the NAVD88 height has been produced for a local tide station then there will be a height that is stated as "NAVD88".

Thanks for the opportunity to comment. Hope this helps.

Best,
Tim

On Mon, Mar 20, 2017 at 5:56 PM, Curdts, Thom <thom_curdts@partner.nps.gov> wrote:

I guess I agree with you, Maria, but I'm including Tim Smith to see what he says.

Hey Tim, do you want to chime in on Maria's original question? Go to the bottom of the thread. Thanks.

From Wikipedia (my bolds):
NAVD 88 was established in 1991 by the minimum-constraint adjustment of geodetic leveling observations in Canada, the United States, and Mexico. It held fixed the height of the primary tidal bench mark, referenced to the International Great Lakes Datum of 1985 local mean sea level height value, at Rimouski, Quebec, Canada. Additional tidal bench mark elevations were not used due to the demonstrated variations in sea surface topography, i.e., that mean sea level is not the same equipotential surface at all tidal bench marks.

The definition of NAVD 88 uses the Helmert orthometric height, which calculates the location of the geoid (which approximates sea level) from modeled local gravity. The NAVD 88 model is based on then-available measurements, and remains fixed despite later improved geoid models.

Hi Maria,

I don't see anything really wrong with this. But I've suggested some changes below that might tighten it up a little. Would it be worth asking the reviewer for specifics?

A. The North American Vertical Datum of 1988 (NAVD88) is a datum that is commonly used in North America. It uses a fixed value for the height of North America's mean sea level. While this is a popular datum for mapping, it has the limitation of being based on the the observed mean sea level at a single location: Rimouski, Canada. In other areas you can expect the local observed mean sea level to differ from mean sea level at Rimouski. For locations such as California, this can result in a significant difference between observed mean sea level and NAVD88. Your natural resource or GIS specialist will likely have further information about your specific location.
Alternatively you can look up the differences in your region by checking the datum information for your nearest tide gauge station: [https://tidesandcurrents.noaa.gov/stations.html?type=Datums](https://tidesandcurrents.noaa.gov/stations.html?type=Datums)

hope that helps,

Thom

Thom,

I'm going through some reviewer edits on my final report. One of my reviewers says that I've described how NAVD88 incorrectly. Could you look at the following text and let me know what I've got wrong or if there is a better way to word this?

"Q. What are the effects of NAVD88 on projections for some parks?

A. The North American Vertical Datum of 1988 (NAVD88) is a datum that is commonly used in North America. It uses a fixed value for the height of the sea level. While this is a popular datum for mapping, it has the limitation that it is based on the tidal benchmark for Rimouski, Canada. As you move further away from this benchmark you can expect actual sea level to differ from the reference benchmark. For locations such as California this can result in a significant difference between observed mean sea level and NAVD88. Your natural resource or GIS specialist will likely have further information about your specific location. Alternatively you can look up the differences in your region by checking the datum information for your nearest tide gauge station: [https://tidesandcurrents.noaa.gov/stations.html?type=Datums](https://tidesandcurrents.noaa.gov/stations.html?type=Datums)

Good morning:

This report "Sea level rise and storm surge projections for the National Park Service" will not be ready for release in March 2017. We will submit it to the Natural Resource Report Series next week (3/ for formatting and to assign the report number. This process will include creating an IRMA (online) record, but the report will not be public until all agree on a release process.

Q. Is there a comms plan?
Q. Is there a briefing paper?

A. There will be a comms plan and a set of talking points. The Comms plan will be developed with Jeff Olson (WASO Comms). If needed, briefings about the report will be held in person or via webinar, etc.

There is a communication team with this project; members are Larry Perez, Ryan Stubblebine, and Matt Holly (All CCRP Comms); Shawn Norton (SOCC); Ann Gallagher (NCRO); Janet Cakir (SERO); Stanton Enomoto (PWRO, former member); Will Elder (GOGA, former member); and Lynda Bell (NRSS-OCRB, former member).

Q. Who did peer review?

A. Peer review was conducted with both internal and external reviewers. Reviewers were selected based on their expertise in one or more fields relating to coastal climate change, sea level change, or storm surge. The following people reviewed the document: Amanda Babson (NPS), Ann Gallagher (NPS), Larry Perez (NPS), Steve Nerem (University of Colorado-IPCC lead on sea level), Bob Glahn (emeritus, NOAA), Doug Marcy (NOAA), Chris Zarvas (NOAA), Rob Thieler (USGS), and Claudia Tebaldi
All peer review comments have been compiled in either spreadsheets as PDFs. Comments covered the entire report.

Q. Is it available to read before it is released?

A copy of the publication will be available to an internal audience prior to release.

Thank you for your interest in this report.

There may be questions about the report.

Here is the first one:

In late March, the NPS will release a peer-reviewed report on projections of sea level rise and storm surge for 118 and 79 coastal parks (respectively). The results are intended to inform park planning, and adaptation and mitigation strategies for lands managed by the NPS. In recent years, the NPS has provided data to parks on a case-by-case basis for localized planning, but this report is a summary of the full analysis that is now complete.

- Is there a comms plan?
- Who did peer review?
- Is there a briefing paper?
- Is it available to read before it is released?

NRSS Weekly Report for the Week of April 10, 2017

GENERAL UPDATES

(EQD; Duplicate of Park Entry) Morristown NHP Vegetation and Deer Management Plan EA: On April 5, we will be distributing, via US Mail, approximately 80 newsletters updating interested individuals and groups on the progress and next steps of the Morristown National Historical Park Vegetation and Deer Management Planning process. These individuals and groups have been involved with the project since its kick-off and have asked to stay informed of the plan’s progress. Specifically, the newsletter will announce the change in the NEPA pathway from an Environmental Impact Statement (EIS) to an Environmental Assessment (EA) due to our finding, after careful study and analysis, that none of the alternatives considered have the potential to result in significant adverse environmental impacts. It will also be the first ungulate management plan to dismiss contraception as a possible alternative to be considered for analysis. See newsletter for more details. (EQD Contact: Dan Niosi, 303-969-2068)

(NSNSD) Girls in STEM Outreach Event: NSNSD will participate in the Girls in STEM Expanding Your Horizons event at Colorado State University on April 8th. Participation includes assisting in hands-on science workshops and staffing a NPS booth. (Katie Nuessly, 970-267-2114)

TECHNICAL ASSISTANCE AND TRAINING

(CCRP) Climate change assistance to Lassen Volcanic NP: Patrick Gonzalez will provide assistance on climate change science and resource management to staff of Lassen Volcanic NP, in collaboration with planners from Denver Service Center, at a Resource Stewardship Strategy workshop April 11-13, 2017 at park headquarters. (Contact patrick_gonzalez@nps.gov)

(GRD) Emergency Rockfall Assistance at Grand Canyon: Staff will be traveling Sunday, April 9, to Grand Canyon National Park on an emergency basis to help park staff determine how best to address rockfalls that have damaged the park’s only waterline this past week. An ongoing rockfall hazard apparently exists that needs geologic consultation. (Contact Eric Bilderback @ 303-969-2154, or eric_bilderback@nps.gov)

(NSNSD) Attendance at NPS Fundamentals: Natural Sounds & Night Skies staff will attend NPS Fundamentals on March 20 - 31. Staff will be learning about the origin of NPS and how the different roles within NPS come together to support the NPS mission. NPS staff will have the opportunity to present an overview of the Natural Sounds & Night Skies Division, including the services and expertise available to parks and regions and how these programs help fulfill the NPS mission of protecting and preserving our natural resources and their enjoyment by visitors. This will be the third staff member attending NPS Fundamentals in the last year. (Contact: Bob Meadows, 970-267-2199)
(WRD) Wetland Restoration Design Charrette, DEWA: In an effort to create park staff buy-in and ownership of a 30-acre design project, WRD staff will generate grading plans that represent design alternatives and modify the alternatives with input from park staff. In addition, WRD staff will conduct a pre-application meeting with state and federal agencies to present the design of another wetland restoration project at DEWA. (Contact: Pete Sharpe, 267 858 1001 or Kevin Noon, 303 969 2815)

UPCOMING NRSS TRAINING AND EVENTS

[Save the Date (All NRSS staff)] Resource Stewardship Strategy (RSS) Presentations, Denver and Fort Collins: On May 3 from 1-2:30 in Denver rooms 435/440 and on May 15 from 10:00-11:30 in Fort Collins Yellowstone Rooms, Chris Church and Don Wojcik from Denver Service Center will give a presentation on the current status and evolution of the RSS process. The National Working Group’s vision is to develop an integrated, strategic resource management tool to help parks achieve their stewardship goals over time. All staff is encouraged to attend the presentation because close collaboration, support and engagement from parks, regions and program offices are critical to the success of this program. Come learn who each division’s representatives are and what their role has been in the process. Contact: Lori Makarick.

PAPERS, PRESENTATIONS AND MEETINGS

(ARD) Lassen Volcanic National Park Resource Stewardship Strategy (RSS) Workshop April 11-13 2017, Mineral, CA: NPS Denver Service Center (DSC) project managers will lead staff from LAVO, PWR, NRSS (BRD, ARD, CRPP, IMD, NSNSD) in the first of two workshops to develop the park's RSS as part of a second round of 15 DSC led pilot RSSs in FY2017. The first workshop will gather existing information on park resources, evaluate key issues, stressors, and threats, identified priority resources and components, and begin setting long-term goals. The second workshop, scheduled May 23-25 2017, will complete RSS development by setting short-term goals and identify and prioritize stewardship activities, including integrated activities that may benefit both natural and cultural resources. (Contact: Jim Cheatham 303-969-2703)

(ARD) Presentation at the Air & Waste Management Association's 2017 Air Quality Conference: Mike Barna will be presenting at the Air and Waste Management - Rocky Mountain States Section (AWMA-RMSS) annual meeting, which will be held in Denver on April 13th. The title of his talk is “Simulating the Contribution of Emissions from Oil and Gas Development to Regional Nitrogen Deposition at National Parks in the Intermountain West.” This 1-day conference provides a forum to discuss current air pollution issues in the western US with regulators, consultants, and researchers. (contact: Mike Barna, 970-491-8692).

(ARD, GRD) NRSS participation at Denver Museum of Nature and Science Free Day Monday April 10: We are using the event to highlight science in the national parks as staff from both divisions will bring hands on activities, educational posters, and Junior Ranger activity books. We will promote Every Kid In a Park, National Park Week, and encourage visitors to find their park with Servicewide and Colorado park maps. We will also set up a “photo booth”
featuring NPS landscapes from Colorado. The event runs from 10 am to 4 pm and the museum expects around 9,000 people to visit that day. (Contact Jason Kenworthy; 303-987-6923)

(BRD) Western Bat Working Group Biennial Meeting in Fort Collins, Colorado: BRD staff will be participating in the Western Bat Working Group meeting held April 11 - 14 in Fort Collins. The WBWG is a partner in the Coalition of North American Bat Working Groups and includes state and federal agencies, universities, and NGOs dedicated to bat research, management and conservation in western US states, Canadian provinces, and northern Mexico. The conference, sponsored in part by NPS, provides opportunities for sharing knowledge and technologies, discussing action plans, and building collaborations for coordinated management of bats. Presentations, panel discussions, break-out sessions and hands-on training for best practices in acoustics and surveillance for white-nose syndrome will be included. (Contact: Michelle Verant, 970-225-3541)

(BRD) Planning meeting for a Bats and Climber Engagement Film: BRD staff will be meeting with Ravenswood Media and other project collaborators on April 10th in Fort Collins to discuss plans for a film funded by a White-nose Syndrome Small Grant provided through the Wildlife Management Institute with funds from the US Fish and Wildlife Service. The film is intended to engage the climbing community in bat conservation and raise awareness of bats and the threats they face, including white-nose syndrome, proposed filming locations include Acadia NP, Devils Tower NM and Yosemite NP. Project collaborators include the parks listed, Idaho Department of Fish and Game, Colorado Natural Heritage Program and Bat Conservation International. (Contact: Michelle Verant, 970-225-3541)

(CCRP) Recently Published Articles of Note: CCRP staff contributed to recent articles featured in Slate and Vox. (Contact: Larry Perez at larry_perez@nps.gov or 970-267-2136.)

(IMD) USGS/BLM workshop: Joe DeVivo will present an overview of the Inventory and Monitoring Program at a jointly-hosted USGS/BLM workshop on April 11, designed to identify and evaluate potential broad-scale indicators to be included as a part of BLM's long-term monitoring program.

(NSNSD) IOA Modification Working Group Call with FAA: On Apr. 13, NSNSD will be talking with FAA policy staff to further work on establishing a process for modifying interim operating authority (IOA) at parks based on NPS request to FAA in order to address the protection of park resources and visitor experience. IOA has already been removed from operators who once had IOA but no longer have an active operating certificate. FAA and NPS are exploring methods to further remove IOA from operators at parks where they have IOA but are not conducting tours. (Vicki Ward 970-225-3563)

(NSNSD) Air Tour Planning: NSNSD will have a conference call with FAA and Department of Transportation Volpe Center on April 12th to discuss the status of ongoing air tour planning efforts, including development of air tour management agreements with commercial operators as authorized under the National Parks Air Tour Management Act of 2000, as amended. (Vicki Ward, 970-267-2117)
THREE WEEKS OUT

(CCRRP) Sometime in April, University of Rhode Island collaborators will publish a new Natural Resource Report entitled Designing and scoping climate change vulnerability assessments for coastal national parks in the Northeast Region: guidance and lessons learned. (Contact: Amanda Babson, NPS)

(CCRRP) Sometime in April, the National Park Service will release a peer reviewed report entitled Sea Level and Storm Surge Projections for 118 National Park Service Units. (Contact: Rebecca Beavers, NPS)

(CCRRP) On April 22-24, the Climate Change Response Program and Indiana Dunes National Lakeshore will host elementary and secondary students for a multi-day Every Kid in a Park event. The immersive learning experience will involve students in citizen science efforts to identify the effects of climate change on park resources. (Contact: Larry Perez, NPS)

(CCRRP) On May 11, CCRP Climate Change scientist Patrick Gonzalez will deliver the plenary session at the 2017 San Francisco Bay Area National Parks Science and Natural Resources Symposium to be held at Golden Gate National Recreation Area. (Contact: Patrick Gonzalez, NPS)

(CCRRP) On May 24-26, the Climate Change Response Program and Cape Cod National Lakeshore will host elementary and secondary students for a multi-day Every Kid in a Park event. The immersive learning experience will involve students in citizen science efforts to identify the effects of climate change on park resources. (Contact Larry Perez, NPS)

Divisions using Google Drive for submissions:  WRD (Frias), NSNSD, EQD (Fox)
Peer review documents are uploaded to the google shared folder for the SL_SS report:

SLR and SS Report Key Messages.docx
Rebecca & Maria,

In preparation for our meeting on March, I wanted to make some headway on a draft InsideNPS post to accompany release.

Have a look below and feel free to edit/comment. I want to make sure this accurately represents your work & findings, and this was admittedly a hasty first stab.

Some of this could easily be worked into a press release, if WASO Comms decides to go that route.

-L

Approximately one-fourth of all National Park Service (NPS) sites are situated on or near the coast. These parks protect a diverse array of ecosystems, historic sites, recreational areas, and infrastructure. From the submerged reefs of Biscayne National Park to the elevated span of the Golden Gate Bridge, coastal parks are experiencing quickening rates of sea level rise. A new report out today helps bring to light the possible extent and timing of sea level change projections for the future.

In *Sea Level Rise and Storm Surge Projections for the National Park Service*, report authors analyze existing datasets from NOAA and the IPCC relative to national park sites. The results illustrate the potential for permanent coastal inundation and flooding due to storm surge under varying greenhouse gas emissions scenarios. Results of the analysis were used to create a suite of storm surge maps for each site included in the study.

Results suggest the parks in the National Capital Region are poised to experience the greatest amount of sea level rise over the next century. Meanwhile, all parks will need to contend with both rising sea levels and the intensification of storms and associated storm surge. This is particularly true of parks along the southeast coast, which have historically taken the brunt of tropical storms and hurricanes.

It is important to note, however, that coastal areas will experience sea level change differently, owing to the variable nature of ocean currents, topography of the coast, and the influence of localized changes in land elevation. The coastline near Jean Lafitte National Park, for example, is likely to experience faster rates of relative sea level due to high rates soil subsidence. Conversely, most Alaskan parks are expected to see continued falling of sea level as the land mass rebounds from the loss of heavy, land-based ice.

The catastrophic damage wrought by Hurricane Sandy in 2012 underscores the need to understand the nature of changing conditions along the coast. Taking stock of trends in sea level change is a necessary precursor to identifying future vulnerabilities and managing risk responsibly. When coupled with earlier work examining infrastructure at risk along the coast, the results of this study can help identify vulnerabilities, prioritize management action, and guide public investments in sustainable projects.

Rebecca: I'm way behind because of some recent computer problems, and am having Lise work with you really quickly before the report is sent to me.

Lise: Give this report a good once-over and talk and work with Rebecca if you need to reformat anything that does not meet NRR standards.

   I have not even opened this file and have no idea how much or little time this will take.

Let me know if you have any questions.

Thanks.

Change of plans. Sorry!

I'll be working on this report instead of Lise.

I need Lise to work on a giant vegetation inventory map that was just sent to me instead.

Thanks.

On Fri, Apr 21, 2017 at 4:23 PM, Johnson, Chalmers-Fagan <fagan_johnson@nps.gov> wrote:

Hello Rebecca, everyone. Hopefully this will only require a few more minutes of your time.

The only reason that this email is long, is to provide additional guidance for what you still need to do (the three steps below), and details about exactly what I changed in your document (optional reading below the three steps).

**Three Remaining Steps**
(Download detailed instructions for all three steps)

**Step 1. Download the updated MS Word file and final and updated MSF at:**

https://drive.google.com/drive/folders/0Bx0uAOormwkIMkYtLTU3M0pUdDQ?usp=sharing

**Maintaining your own copy of the final MSF is optional. We maintain multiple archived versions.**

**Step 2. Double-check and approve my updates and have Fagan export the final to PDF (Rebecca and Fagan).**
a) Make your absolute final edits (if any), and send the **VERY FINAL** version of the .docx file back to Fagan.

If you want to know exactly what we updated in your report (optional), proceed to the ***Report Updates and Changes*** section below.

Make sure that there are no more changes when you send the report to Fagan. The sub-step below takes about 2-3 minutes per page. Changes after that point usually require starting over with the entire process (re-tagging all pages and not just the ones with changes).

b) **When all edits are final, Fagan will** export the final to PDF format and manually check fix the HTML-type tags on each page to meet current Section 508 of the Rehabilitation Act standards, such that the final document to be read aloud correctly by special screen readers for the visually and cognitively impaired.

---

Step 3. Activate the draft IRMA record that I created for you, and upload the final PDF (Fagan).

a) Go to this address to open the draft Data Store record that I created for you:

https://irma.nps.gov/DataStore/Reference/Profile/2239974

b) Click the Actions drop down menu near the top right of the screen and click Edit and update the Core and Subjects and Keywords information as you desire

**Note:** The Data Store search engine only searches on the bibliographic information you enter here. It does not search anything located inside any uploaded digital files.

c) When you are finished updating the Data Store bibliographic information, click the Activate button at the bottom-right of the page to save your changes and make the record visible to the public.

d) Go to the Files and Links tab. On the Add drop down menu, choose the Digital File. Use the file upload tools to upload the final PDF and Activate it (the PDF Holding also has to be Active to be downloadable).

(Download detailed instructions for all three steps)
**Everything below this point is just for people that really want to know EXACTLY what we edited and updated in their report.**

***New Report Numbers and Citation (new/important information below highlighted in yellow):***

**Series Name Number:**
Natural Resource Report NPS/NRSS/NRR—2017/1425

**Citation (on shown on page ii):**
- we use sentence case here (only first letters, proper names, and acronyms capitalized).

A good rule-of-thumb for proper names that we use, is whether or not you can send a physical letter through the mail to that entity.

You cannot send a letter to: Sea Level Rise

But, you can send a letter to the Sea Level Rise Program, or Office, or Committee.

- if you update the series name/number with the one that I gave you above, your citation becomes:

**TIC Number:** 999/137852

*** Report Updates and Changes : here is what I updated and changed in your report.***

How closely the rest of the report adheres to the "best practices" format and layout standards presented in our document templates, is up to the official Peer Review Manager for that report (Cat or John).

**Front Cover and Title Pages (we are only this picky about the front and back cover pages):**
- set your page margins to 0.75-inch on the left, top, and right; and 1-inch on the bottom (yours were 1-inch on all sides).
- updated the series name/number with the one that I gave you above.
- made sure that your cover image had alternate text (Section 508 - matches the caption on the following page).
- set the publication month and year to now.
Page ii:
- updated the sixth paragraph to the newer 2017 template standards (DOI/NPS prefers that we just add the hyperlink to the name of the webpage or website, and not spell-out the URL separately).
- updated the official report citation with the information that I gave you above.
- incorporated your new TIC number and the current month and year into the last line on the page.

Page Numbers: Were showing up in different locations on different pages, so I deleted and re-added them to all pages.

This is a common MS Word bug that occurs whenever multiple versions of MS Word edit or create pages inside the same document (especially when more than two major versions were used).

First Order Headings: Set them all to begin at the top of a new page.

All first order headings must begin at the top of a new page.

The only exception to this rule is if you already have a first order heading at the top of a new page, then you may also place additional first order headings lower on the very same page.

Lists of Contents, Figures, Tables, Photos, and Appendices:
- checked for common software bugs. These were fine.
- updated the page numbers in the tables when I was finished with everything else.

Figures - Made sure that figures:
- stayed inside the page margins (Section 508 and document stability). They were fine.
- were in-line with text (no text wrapping—avoids export to PDF issues and prevents document crashes while editing).
- used consistent and predictable page placement in general (center-justified, same vertical distance from captions, etc.).

Tables - Made sure that:
- the table caption was located on the text line immediately above the table (and not in a table cell—avoids export to PDF issues).
- tables stayed inside the page margins (avoids export to PDF issues and prevents document crashes while editing). For tables that were larger than the page, I either:

  a) Shrank the size of the table to fit inside the page margins.
  b) Changed the page orientation to landscape orientation.

- since this was an NRSS report, reorganized tables to make them more Section 508 compliant.
- replaced mid-table multiple column header rows with additional left-hand columns.

- made sure that all captions and table notes were repeated above and below all sub-tables for tables that spanned multiple pages.

- split and merged cells as needed such that all table cells would be read aloud correctly by screen readers for the visually and cognitively impaired (that software was designed to read tables aloud that are set up more like a spreadsheet).

- used a consistent and predictable layout scheme (left-justified, same border and background treatments, etc.).

**Inside Back and Outside Back Cover Pages:**

- made sure that the inside back cover occurred on an odd-numbered page.

  This insures that the outside back cover is the absolute final printed page (no extra blank page).

- incorporated your new TIC number and the current month and year into the last line on the inside cover page.

**That's it!**

"What's another word for Thesaurus?" Steven Wright
HI Larry, Patrick & Cat:

We received the next version of the report from Fagan. I'll send you our revised version of the document soon (later today or Tuesday). Do we want the full science & communication teams to get an "absolute final review opportunity" or just a courtesy "heads up"?

Larry: When should we give Jeff Olson a "Heads Up"?

Status: While the report is ready (and may be considered ready for publication in April), we should make the data available to readers along with the report release in an ideal world. That is a separate process & will require some funding to get the web interface "back" online. At one point the interface was online in a beta version, and more work is needed to keep pace with our great web updates. The work is helping to integrate these data with a variety of park planning tools, etc. It is not a mere data repository/query platform.

Have a great day.

Subject: Sea Level Rise Report Final Layout Policy Review
To: Rebecca Beavers <rebecca_beavers@nps.gov>, John Gross <john_gross@nps.gov>, Cat Hoffman <cat_hawkins_hoffman@nps.gov>, Patrick Gonzalez <patrick_gonzalez@nps.gov>
Cc: Tani Hubbard <tani_hubbard@nps.gov>, Margaret Beer <margaret_beer@nps.gov>

Hello Rebecca, everyone. Hopefully this will only require a few more minutes of your time.

   The only reason that this email is long, is to provide additional
guidance for what you still need to do (the three steps below), and details about exactly what I changed in your document (optional reading below the three steps).

Three Remaining Steps
(Download detailed instructions for all three steps)

Step 1. Download the updated MS Word file and final and updated MSF at:

https://drive.google.com/drive/folders/0Bx0uAOormwkIMkYtLTU3M0pUdDQ?usp=sharing

**Maintaining your own copy of the final MSF is optional. We maintain multiple archived versions.

Step 2. Double-check and approve my updates and have Fagan export the final to PDF (Rebecca and Fagan).

a) Make your absolute final edits (if any), and send the VERY FINAL version of the .docx file back to Fagan.

If you want to know exactly what we updated in your report (optional), proceed to the ***Report Updates and Changes section below.

Make sure that there are no more changes when you send the report to Fagan. The sub-step below takes about 2-3 minutes per page. Changes after that point usually require starting over with the entire process (re-tagging all pages and not just the ones with changes).

b) When all edits are final, Fagan will export the final to PDF format and manually check fix the HTML-type tags on each page to meet current Section 508 of the Rehabilitation Act standards, such that the final document to be read aloud correctly by special screen readers for the visually and cognitively impaired.

Step 3. Activate the draft IRMA record that I created for you, and upload the final PDF (Fagan).

a) Go to this address to open the draft Data Store record that I created for you:

https://irma.nps.gov/DataStore/Reference/Profile/2239974

b) Click the Actions drop down menu near the top right of the screen
and click *Edit* and update the Core and Subjects and Keywords information as you desire.

**Note:** The Data Store search engine only searches on the bibliographic information you enter here. It does not search anything located inside any uploaded digital files.

c) When you are finished updating the Data Store bibliographic information, click the *Activate* button at the bottom-right of the page to save your changes and make the record visible to the public.

d) Go to the *Files and Links* tab. On the *Add* drop down menu, choose the *Digital File*. Use the file upload tools to upload the final PDF and *Activate* it (the PDF Holding also has to be *Active* to be downloadable).

(*Download detailed instructions for all three steps*)

***Everything below this point is just for people that really want to know EXACTLY what we edited and updated in their report.***

**New Report Numbers and Citation** *(new/important information below highlighted in yellow):*

**Series Name Number:**
Natural Resource Report NPS/NRSS/NRR—2017/1425

**Citation (on shown on page ii):**
- we use sentence case here (only first letters, proper names, and acronyms capitalized).

> A good rule-of-thumb for proper names that we use, is whether or not you can send a physical letter through the mail to that entity.

*You cannot send a letter to: Sea Level Rise*

*But, you can send a letter to the Sea Level Rise Program, or Office, or Committee.*

- if you update the series name/number with the one that I gave you above, your citation becomes:

*** Report Updates and Changes: here is what I updated and changed in your report.

How closely the rest of the report adheres to the "best practices" format and layout standards presented in our document templates, is up to the official Peer Review Manager for that report (Cat or John).

Front Cover and Title Pages (we are only this picky about the front and back cover pages):
- set your page margins to 0.75-inch on the left, top, and right; and 1-inch on the bottom (yours were 1-inch on all sides).
- updated the series name/number with the one that I gave you above.
- made sure that your cover image had alternate text (Section 508 - matches the caption on the following page).
- set the publication month and year to now.

Page ii:
- updated the sixth paragraph to the newer 2017 template standards (DOI/NPS prefers that we just add the hyperlink to the name of the webpage or website, and not spell-out the URL separately).
- updated the official report citation with the information that I gave you above.
- incorporated your new TIC number and the current month and year into the last line on the page.

Page Numbers: Were showing up in different locations on different pages, so I deleted and re-added them to all pages.

This is a common MS Word bug that occurs whenever multiple versions of MS Word edit or create pages inside the same document (especially when more than two major versions were used).

First Order Headings: Set them all to begin at the top of a new page.

All first order headings must begin at the top of a new page.

The only exception to this rule is if you already have a first order heading at the top of a new page, then you may also place additional first order headings lower on the very same page.

Lists of Contents, Figures, Tables, Photos, and Appendices:
- checked for common software bugs. These were fine.
- updated the page numbers in the tables when I was finished with everything else.

Figures - Made sure that figures:
- stayed inside the page margins (Section 508 and document stability).
They were fine.
- were in-line with text (no text wrapping—avoids export to PDF issues and prevents document crashes while editing).
- used consistent and predictable page placement in general (center-justified, same vertical distance from captions, etc.).

Tables - Made sure that:
- the table caption was located on the text line immediately above the table (and not in a table cell—avoids export to PDF issues).
- tables stayed inside the page margins (avoids export to PDF issues and prevents document crashes while editing). For tables that were larger than the page, I either:
  a) Shrank the size of the table to fit inside the page margins.
  b) Changed the page orientation to landscape orientation.
- since this was an NRSS report, reorganized tables to make them more Section 508 compliant.
  - replaced mid-table multiple column header rows with additional left-hand columns.
  - made sure that all captions and table notes were repeated above and below all sub-tables for tables that spanned multiple pages.
  - split and merged cells as needed such that all table cells would be read aloud correctly by screen readers for the visually and cognitively impaired (that software was designed to read tables aloud that are set up more like a spreadsheet).
- used a consistent and predictable layout scheme (left-justified, same border and background treatments, etc.).

Inside Back and Outside Back Cover Page s:
- made sure that the inside back cover occurred on an odd-numbered page.
  
  This insures that the outside back cover is the absolute final printed page (no extra blank page).
- incorporated your new TIC number and the current month and year into the last line on the inside cover page.

That's it!

Subject: Sea Level Rise Report Final Layout Policy Review
To: Rebecca Beavers <rebecca_beavers@nps.gov>, John Gross <john_gross@nps.gov>, Cat Hoffman <cat_hawkins_hoffman@nps.gov>, Patrick Gonzalez <patrick_gonzalez@nps.gov>
Cc: Tani Hubbard <tani_hubbard@nps.gov>, Margaret Beer <margaret_beer@nps.gov>

Hello Rebecca, everyone. Hopefully this will only require a few more minutes of your time.
The only reason that this email is long, is to provide additional guidance for what you still need to do (the three steps below), and details about exactly what I changed in your document (optional reading below the three steps).

**Three Remaining Steps**
(Download detailed instructions for all three steps)

**Step 1. Download the updated MS Word file and final and updated MSF at:**

https://drive.google.com/drive/folders/0Bx0uAOormwkIMkYtLTU3M0pUdDQ?usp=sharing

**Maintaining your own copy of the final MSF is optional. We maintain multiple archived versions.**

**Step 2. Double-check and approve my updates and have Fagan export the final to PDF (Rebecca and Fagan).**

a) **Make your absolute final edits (if any), and send the VERY FINAL version of the .docx file back to Fagan.**

If you want to know exactly what we updated in your report (optional), proceed to the ***Report Updates and Changes section below.

**Make sure that there are no more changes when you send the report to Fagan. The sub-step below takes about 2-3 minutes per page. Changes after that point usually require starting over with the entire process (re-tagging all pages and not just the ones with changes).**

b) **When all edits are final, Fagan will** export the final to PDF format and manually check fix the HTML-type tags on each page to meet current Section 508 of the Rehabilitation Act standards, such that the final document to be read aloud correctly by special screen readers for the visually and cognitively impaired.

**Step 3. Activate the draft IRMA record that I created for you, and upload the final PDF (Fagan).**

a) Go to this address to open the draft Data Store record that I created for you:

https://irma.nps.gov/DataStore/Reference/Profile/2239974
b) Click the Actions drop down menu near the top right of the screen and click Edit and update the Core and Subjects and Keywords information as you desire

**Note:** The Data Store search engine only searches on the bibliographic information you enter here. It does not search anything located inside any uploaded digital files.

c) When you are finished updating the Data Store bibliographic information, click the Activate button at the bottom-right of the page to save your changes and make the record visible to the public.

d) Go to the Files and Links tab. On the Add drop down menu, choose the Digital File. Use the file upload tools to upload the final PDF and Activate it (the PDF Holding also has to be Active to be downloadable).

(Download detailed instructions for all three steps)

***Everything below this point is just for people that really want to know EXACTLY what we edited and updated in their report.***

**New Report Numbers and Citation (new/important information below highlighted in yellow):**

**Series Name Number:**
Natural Resource Report NPS/NRSS/NRR—2017/1425

**Citation (on shown on page ii):**
- we use sentence case here (only first letters, proper names, and acronyms capitalized).

A good rule-of-thumb for proper names that we use, is whether or not you can send a physical letter through the mail to that entity:

**You cannot** send a letter to: Sea Level Rise

**But, you can** send a letter to the Sea Level Rise Program, or Office, or Committee.

- if you update the series name/number with the one that I gave you above, your citation becomes:

TIC Number: 999/137852

*** Report Updates and Changes : here is what I updated and changed in your report.***

How closely the rest of the report adheres to the "best practices" format and layout standards presented in our document templates, is up to the official Peer Review Manager for that report (Cat or John).

Front Cover and Title Pages (we are only this picky about the front and back cover pages):
- set your page margins to 0.75-inch on the left, top, and right; and 1-inch on the bottom (yours were 1-inch on all sides).
- updated the series name/number with the one that I gave you above.
- made sure that your cover image had alternate text (Section 508 - matches the caption on the following page).
- set the publication month and year to now.

Page ii:
- updated the sixth paragraph to the newer 2017 template standards (DOI/NPS prefers that we just add the hyperlink to the name of the webpage or website, and not spell-out the URL separately).
- updated the official report citation with the information that I gave you above.
- incorporated your new TIC number and the current month and year into the last line on the page.

Page Numbers: Were showing up in different locations on different pages, so I deleted and re-added them to all pages.

This is a common MS Word bug that occurs whenever multiple versions of MS Word edit or create pages inside the same document (especially when more than two major versions were used).

First Order Headings: Set them all to begin at the top of a new page.

All first order headings must begin at the top of a new page.

The only exception to this rule is if you already have a first order heading at the top of a new page, then you may also place additional first order headings lower on the very same page.

Lists of Contents, Figures, Tables, Photos, and Appendices:
- checked for common software bugs. These were fine.
- updated the page numbers in the tables when I was finished with everything else.
**Figures - Made sure that figures:**
- stayed inside the page margins (Section 508 and document stability). They were fine.
- were in-line with text (no text wrapping—avoids export to PDF issues and prevents document crashes while editing).
- used consistent and predictable page placement in general (center-justified, same vertical distance from captions, etc.).

**Tables - Made sure that:**
- the table caption was located on the text line immediately above the table (and not in a table cell—avoids export to PDF issues).
- tables stayed inside the page margins (avoids export to PDF issues and prevents document crashes while editing). For tables that were larger than the page, I either:
  a) Shrank the size of the table to fit inside the page margins.
  b) Changed the page orientation to landscape orientation.
- since this was an NRSS report, reorganized tables to make them more Section 508 compliant:
  - replaced mid-table multiple column header rows with additional left-hand columns.
  - made sure that all captions and table notes were repeated above and below all sub-tables for tables that spanned multiple pages.
  - split and merged cells as needed such that all table cells would be read aloud correctly by screen readers for the visually and cognitively impaired (that software was designed to read tables aloud that are set up more like a spreadsheet).
- used a consistent and predictable layout scheme (left-justified, same border and background treatments, etc.).

**Inside Back and Outside Back Cover Pages:**
- made sure that the inside back cover occurred on an odd-numbered page.
  
  This insures that the outside back cover is the absolute final printed page (no extra blank page).
- incorporated your new TIC number and the current month and year into the last line on the inside cover page.

**That's it!**

Thanks.

Yes, right after I sent you that note I saw that you BCC:d me and weren't asking for a review anyhow.

Thanks for the heads up.

Looking forward to see the SLR on Web/ GIS!

RB,

Have not had much time to look at this. Gave it a quick scan. Looks ok for what it does — i.e., bathtub model with lower-than-generally-accepted-and-non-probabilistic SLR scenarios. What is the expected lifetime of this document? What's next? There are bodies of literature and newer data and models that could begin to get at this more realistically.

Nice work getting this incremental step done.

Hi RT:

This document is a first opportunity to get a consistent SLR dataset across all coastal parks. The next step is uncertain; largely due to budget uncertainties. Of primary importance is improving on relative land movements.

For specific locations (FL, NY, CA, WA, OR, and more) more detailed information has been and will be available into the future. For places such as NW Alaska, there is no major push for more detailed info so next steps are uncertain.

I'm all ears on future opportunities to improve on this work on a park/region, or other basis.

Thank you for your effort and time to serve on the science team for this project.

It's that time for a final check prior to publication of:

https://drive.google.com/drive/folders/0B2z-WBMLTvtHTFFpOVJjY3U0Snc?usp=sharing

The NPS Sea Level and Storm Surge Projections Report report is available in the google drive folder and ready for the following Next Steps:

- Final check by co-authors Patrick Gonzalez and Cat Hawkins Hoffman.
- Final check by Science and Communication Team Members. (Babson, Cakir, Gallagher, Holly, Norton, Perez, Thieler (USGS))
- If you have edits or will not comment please notify Rebecca.
- Once complete, we will publish and post on IRMA with internal NPS access(initially & by 4/28 if we want to keep April 2017 text in report)

Plan for Release
Website updates (Matt Holly)
Rebecca Beavers and Larry Perez will coordinate release plans through Jeff Olson. Two paths forward are 1) internal release and 2) external release.

**Co-authors/Communication team members: please review/edit these documents** that will be used to guide the release process.

[https://drive.google.com/open?id=0B2z-WBMLTvtHMXhvZjFaRVZxYXM](https://drive.google.com/open?id=0B2z-WBMLTvtHMXhvZjFaRVZxYXM)

Status: the provided manuscript represents:

- Fagan's NRR series review that includes some reformatting of margins and some tables. (completed 4/21)
- Final edits to address comments from Ann Gallagher as presented on 4/19 communication team call. (completed 4/24)
- Content check by Maria Caffrey and Rebecca Beavers. (completed 4/25)

Thank you.

forgot...

I haven't read the media information, but if you and Larry are compiling this in conjunction with Jeff, I'm sure it's fine.

You were a tremendous help to the project!

We will likely roll this out with some regional webinars where we introduce the report and answer any questions folks have. I hope you don't mind if we continue to call on you for help/advice when we get to that stage? You really have a good handle on how people are likely to respond. Your advice has been especially helpful in delivering a product that everyone can understand.

My only comment this time around applies to this question and answer.

**Q. Why don’t you recommend that I add storm surge numbers on top of the sea level change numbers?**

**A.** Higher sea level and permanent inundation will change the way waves propagate within a basin in the future. Sea level change is expected to have a significant impact on the geomorphology of the coastline. Changing water levels will lead to areas of greater erosion in some areas as well as increasing accretion in other places. As sea level changes, the fluid dynamics of a particular region will also change. This is not something NOAA takes into account in their SLOSH model.

I suggest an example of what is meant by fluid dynamics – wave size, tidal distance…

Yours,

Ann

Rebecca,

I have made the change that Ann suggested. I think that's all of the revisions done. The final document can be found here: N:\GRD\Programs\Climate Change - Beavers & Brunner\Caffrey Sea Level Projections\Final report\2017_04 NRSS Layout Reviewed

It is called "Sea Level Change Report_final_fagan_final_May 11.docx"

</table>
3 33 whole section It is not very clear if local subsidence was taken into account for all of these sites? The SLR scenarios should be based on locals relative sea level rise. At the very least, choosing closest tide gauge and using the USACE SLR Calculator would result in more accurate local scenarios if you were to use the NCA scenarios, or just use the subsidence values in the equations to extrapolate future sea level rise. I fear not taking into account local subsidence will result in number too low for the future scenarios.

This is dis 1/11/17 Marcy

3 33 whole section The highest SLR scenario used is the RCP 8.5 by 2100 which only estimates ~0.8m of Sea Level Rise. The upper end of the NCA3 scenarios was 2.0m and the NCA4 range is likely to go up to 2.5m for the 2100 worse case RCP 8.5 scenario. I think your SLR estimates are too low for future planning.

Ok. This 1/11/17 Marcy

6 15 whole section Please check the descriptions of the P-Surge, MEOWS, and MOMs. P-Surge is used for probabilistic real-time runs during landfalling storms and produces an exceedence probability. The MEOWS and MOMs in the SLOSH display program were not derived from P-Surge and have no probability associated with them. The MEOWS are a worst case basin snapshot for a particular storm category, forward speed, trajectory, and initial tide level, incorporating uncertainty in forecast landfall location. These products are compiled when a SLOSH basin is developed or updated. MEOWS are not storm specific and are available to view in the SLOSH display program for all operational basins. No single hurricane will produce the regional flooding depicted in the MEOWS. Instead, the product is intended to capture the worst case high water value at a particular location for hurricane evacuation planning.

MOMs provide a worst case snapshot for a particular storm category under "perfect" storm conditions. Each MOM considers combinations of forward speed, trajectory, and initial tide level. These products are compiled when a SLOSH basin is developed or updated. As with MEOWS, MOMs are not storm specific and are available to view in the SLOSH display program for all operational basins. No single hurricane will produce the regional flooding depicted in the MOMs. Instead, the product is intended to capture the worst case high water value at a particular location for hurricane evacuation planning. The MOMs are also used to develop the nation’s evacuation zones. Long story short is that MOMs are used for worse case evacuation planning and are not in any way related to the 100 year or 1% chance storm and thus should not be compared to the Tebaldi et al, 2012 numbers.

This has 1/11/17 Marcy

6 15 whole section Using MOMs can be problematic because in the SLOSH display program there are often mean tide and high tide runs, but the various basins can different amounts of tide and different tide scenarios, based on what the State Partners wanted modeled for their state Hurricane Evacuation Study. Also where basins overlap there will be non-matching values. Choosing the correct basin value is often a judgement call. NHC has recently put out a National MOM product and they are working on a version 2 and they plan to make the GIS data available. I suggest you contact NHC and try to access this data to improve your study results.

http://noaa.maps.arcgis.com/apps/StorytellingTextLegend/index.html?appid=b1a20ab5ee149085bafe059635a82ee

This goes 1/11/17 Marcy

9 9 10 Tebaldi uses MHHW to reference the extreme surge values...and the mapping for the SLR projections was relateive to MHHW. Make sure datums are consistent.

Ok 1/11/17 Marcy

9 16 16 SLOSH uses a multiple scenario approach...not probabilistic.

Changed 1/11/17 Marcy

10 31 36 The Storm surge layers were not in the map viewer. I could not find where to download the GIS data. Also I noticed the maps for the high SLR scenario for RCP 8.5 are comparable to the NOAA SLR viewer maps for around 2FT above MHHW. I think this is too low of a scenario for 2100 planning. We have reached 2FT above MHHW during high frequency king tide / perigean tide events in Charleston, SC.

See prev 1/11/17 Marcy

12 11 27 Figure 4. Does this include the Gulf Coast? Seems like the number should be much higher in the Gulf based on the very high SLR trends in Louisiana vs. the East Coast.

The Gulf 1/11/17 Marcy
Discussion: need to add a description of the difference between using SLOSH MOMs worse case scenarios and Tebaldi numbers for West Coast. These really are not comparable. The Tebaldi numbers are based on the work of NOAA (Zervis) which are based on 1% water levels at the tide gauges. These numbers will also not match FEMA coastal flood studies because wave effects are not included. The SLOSH MOMs are often way higher than the 1% flood. For example, in Charleston, SC the 1% chance water level at the Charleston tide gauge is ~7.5FT. The category 1 MOM is that high. Going out to Cat 2-5 will produce surge value way above the 1% chance. So comparing SLOSH vs. Tebaldi numbers isn’t really valid. One is based on probabilistic analysis of historical data and the other is on 4500 or so scenario runs and having a cumulative peak value. In many cases in the east and gulf coast the 1% chance FEMA BFE is only a Cat 1 to Cat 2 MOM value.

How were the SLOSH results mapped? There are methods out there from the USACE for doing this for HES studies. http://www.northerngulfinstitute.org/impact/resources/inundationWorkshop/scott.pdf

SLR mapping was done using MHHW but was that converted to NAVD88 to match the DEMs? Just wanting to make sure all the map legend values are showing correct height relative to the same datum for both sets of maps.

Concern: Will the general reader know that 1/100 is rare while 1/500 is even more rare? Maybe a modifier here would help.

If you write: Melting sea ice is not a cause of sea-level rise. The volume of water in the sea remains the same whether the water is...
My only comment this time around applies to this question and answer. Q. Why don’t you recommend that I add storm surge numbers on top of the sea level change numbers? A. Higher sea level and permanent inundation will change the way waves propagate within a basin in the future. Sea level change is expected to have a significant impact on the geomorphology of the coastline. Changing water levels will lead to areas of greater erosion in some areas as well as increasing accretion in other places. As sea level changes, the fluid dynamics of a particular region will also change. This is not something NOAA takes into account in their SLOSH model.
Can you check the report citations (again?)

Hi Rebecca,

FYI - this report is great, I wanted to let you know I just noticed a couple of missing citations (Nerem was one), so you might want to see if someone can comb through the report if it isn't finalized.

169 Answers about climate projections and flooding.....pdf
Hi Marcy,

Maria Caffrey and colleagues have conducted spatial analyses of sea level rise and storm surge for coastal national parks. I’ve attached for you a draft of the report. She provides quantitative results by individual park. The method is the same for all the parks.

NOAA has conducted spatial analyses of sea level rise for the entire U.S.:

NOAA Sea level rise viewer
https://coast.noaa.gov/slr

and coastal flood exposure for the east coast:

Coastal Flood Exposure Mapper
https://coast.noaa.gov/floodexposure/#/map

The NPS and NOAA results certainly go beyond the old FEMA flood maps. Maria's spatial outputs are broadly similar to the NOAA outputs, but Maria used the IPCC scenarios, while NOAA used non-standard U.S. scenarios.

I hope that your presentations go well for you!

Patrick

-----------------------------------
Hi Patrick,

This is probably an enormous question - are there models or sources of data or approaches you would recommend for a state agency wanting to get a better understanding of future flood risks?

Perhaps in other words - sources of data or analysis beyond the FEMA flood risk maps?

Reason for asking - Cultural Resources Technical Preservation Services/State Tribal Local Planning and Grants programs are in the process of developing a new Preservation Brief that will provide guidance and standards for historic property owners who are planning or required to elevate those historic buildings. We're now preparing to do a series of three workshops in different parts of the country to listen to and work with State Historic Preservation Offices, as part of testing and collecting info that will go into the Brief.

I've been asked to give a climate change introduction for each workshop - with the general theme of how climate change is contributing to flood risk and sea level rise, and making the point that these risks are not going away, and that threats that pose these risks are likely to become more unpredictable.

I have some understanding of how NPS has been trying to track and model sea level rise (Maria Caffrey's work, Rob Young's team, for example). But as the nature of flooding risk can be highly specific to individual locations, I don't really have sense of what NPS is doing overall to capture it. So -- I guess that's my real question - do we have a method overall? Or have we been assessing it on a park-by-park basis?

I'd be grateful for thoughts or suggestions you might have. I need to send a set of slides off to the rest of the team by end of next week (26th), so if you're able to send on thoughts before then, that would be great.

Thank you so much,
Marcy

Natural Resource Stewardship and Science
Fort Collins, Colorado
The National Park Service, Natural Resource Stewardship and Science office in Fort Collins, Colorado, publishes a range of reports that address natural resource topics. These reports are of interest and applicability to a broad audience in the National Park Service and others in natural resource management, including scientists, conservation and environmental constituencies, and the public.

The Natural Resource Report Series is used to disseminate comprehensive information and analysis about natural resources and related topics concerning lands managed by the National Park Service. The series supports the advancement of science, informed decision-making, and the achievement of the National Park Service mission. The series also provides a forum for presenting more lengthy results that may not be accepted by publications with page limitations.

All manuscripts in the series receive the appropriate level of peer review to ensure that the information is scientifically credible, technically accurate, appropriately written for the intended audience, and designed and published in a professional manner.

This report received formal peer review by subject-matter experts who were not directly involved in the collection, analysis, or reporting of the data, and whose background and expertise put them on par technically and scientifically with the authors of the information.

Views, statements, findings, conclusions, recommendations, and data in this report do not necessarily reflect views and policies of the National Park Service, U.S. Department of the Interior. Mention of trade names or commercial products does not constitute endorsement or recommendation for use by the U.S. Government.

This report is available in digital format from the Climate Change Response Program website and the Natural Resource Publications Management website. To receive this report in a format optimized for screen readers, please email irma@nps.gov.

Figures

Figure 1. Sea level trends for the United States based on Zervas (2009), for all available data through 2015. Each dot represents the location of a long-term (>30 years) tide gauge station. Green dots represent stations that are experiencing the average global rate of sea level change. Stations depicted by yellow to red dots are experiencing greater than the global average (primarily driven by regional subsidence) and blue to purple dots are stations experiencing less than the global average (due to isostatic rebound or other tectonically-driven factors). Source: https://tidesandcurrents.noaa.gov/sltrends/slrmap.htm

Figure 2. An example of how areas of inundation appear in ArcGIS. In this example for the Toms Cove area of Assateague Island National Seashore, areas of inundation (RCP4.5 2050) appear in blue. Green shading indicates other low lying areas that are blocked from inundation by some impediment, but nonetheless could experience flooding should the physical barrier be removed or breached.

Figure 3. An example of the extent of an operational basin shown in NOAA’s SLOSH display program (http://www.nhc.noaa.gov/surge/slosh.php). The black area is the full extent of the operational basin for Chesapeake Bay.

Figure 4. Projected future sea level by NPS region for 2100 under RCP8.5 (the “business as usual” climate change scenario). Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each region.

Executive Summary

Changing relative sea levels and the potential for increasing storm surges due to anthropogenic climate change present challenges to national park managers. This report summarizes work done by the University of Colorado in partnership with the National Park Service (NPS) to provide sea level rise and storm surge projections to coastal area national parks using information from the United Nations Intergovernmental Panel on Climate Change (IPCC) and storm surge scenarios from National Oceanic and Atmospheric Administration (NOAA) models. This research is the first to analyze IPCC and NOAA projections of sea level and storm surge under climate change for U.S. national parks. Results illustrate potential future inundation and storm surge due to climate change under four greenhouse gas emissions scenarios. In addition to including multiple scenarios, the analysis considers multiple time horizons (2030, 2050 and 2100). This analysis provides sea level rise projections for 118 park units and storm surge projections for 79 of those parks.

Within the National Park Service, the National Capital Region is projected to experience the highest average rate of sea level change by 2100. The coastline adjacent to Wright Brothers National Memorial in the Southeast Region is projected to experience the highest sea level rise by 2100. The Southeast Region is projected to experience the highest storm surges based on historical data and NOAA storm surge models.

These results are intended to inform park planning and adaptation strategies for resources managed by the National Park Service.

Acknowledgments

This project was awarded funds through the NPS Servicewide Comprehensive Call (FY2013–2015) and augmented by funds from the Natural Resource Stewardship and Science Directorate’s Geologic Resources Division and Climate Change Response Program. We would like to thank the members of the communication advisory team (Rebecca Beavers, Lynda Bell, Maria Caffrey, Janet Cakir, Will Elder, Stanton Eno moto, Ann Gallagher, Matt Holly, Shawn Norton, Larry Perez, and Ryan Stubblebine) and science advisory team (Amanda Babson, Rebecca Beavers, Maria Caffrey, Patrick Gonzalez, Steve Nerem, and Rob Thieler) for their time and input into this project.

We would also like to thank Susan Teel and Caroline Rohe at Gulf Islands National Seashore for assistance in designing two wayside exhibits. Likewise, we thank Julie Whitbeck, Aleutia Scott, Kristy Wallisch, and Stacy Meyers for helping design, review, and install a wayside at Jean Lafitte National Historical Park and Preserve. Elizabeth Rogers and Kathy Krause helped design a wayside for Fire Island National Seashore. Doug Wilder, Dorothy Friday, and Neal Jander designed the online map viewer. We would also like to thank Jason Kenworthy, Rebecca Port, Michael Barthelmes, Bob Glahn, Doug Marcy, Chris Zervas, and Claudia Tebaldi for their assistance in editing and reviewing this document. Finally, we thank the National Oceanic and Atmospheric Administration for and the Intergovernmental Panel on Climate Change for providing the respective storm surge and sea level rise data cited throughout this document.

List of Terms

The following list of terms are defined here as they will be used in this report.

**Bathtub model:** A simplification of the sea as bathtub of water to simulate a change in water level relative to the land. This model does not include other factors such changes in erosion or accretion that change alter the geometry of the coastline.

**Flooding:** The temporary occurrence of water on the land.

**Inundation:** The permanent impoundment of water on what had previously been dry land.

**Isostatic rebound:** A change in land level caused by a change in loadings on the Earth’s crust. The most common cause of isostatic rebound is the loading of continental ice during the Last Glacial Maximum in North America. The North American land surface is still returning to equilibrium after the melting of this continental ice in an effort to return to equilibrium with its original pre-loading state.

**National Park Service unit:** Property owned or managed by the National Park Service.

**Relative sea level:** Where the water level can be found compared to some reference point on land. This term is most frequently used in discussion of changes in relative sea level. A change in relative sea level could be caused by a change in water volume or a change in land level (or some combination of these two factors).
Sea level: The average level of the seawater surface.

Sea level change: This term is frequently used in reference to relative sea level change. This is the product of two main factors, 1) an increase in the volume of ocean water, and 2) a change in land level. These two factors can be broken down further into other drivers that will be discussed in greater detail in other sections. This term is sometimes mistakenly confused with the term sea level rise.

Sea level rise: An increase in sea level. This is the result of an increase in ocean water volume caused principally by melting continental ice and thermal expansion. This term is not to be confused with increasing relative sea level, which can also be caused by decreasing land levels.
Introduction

Global sea level is rising. While sea levels have been gradually rising since the last glacial maximum approximately 21,000 years ago (Clark et al. 2009, Lambeck et al. 2014), anthropogenic climate change has significantly increased the rate of global sea level rise (Grinsted et al. 2009, Church and White 2011, Slangen et al. 2016, Fasullo et al. 2016). Human activities continue to release carbon dioxide (CO₂) into the atmosphere, causing the Earth’s atmosphere to warm (IPCC 2013, Mearns et al. 2013, Melillo et al. 2014). Continued warming of the atmosphere will cause sea levels to continue to rise, which will have a significant impact on how we protect and manage our public lands. The rate of warming depends on numerous factors considered by the Intergovernmental Panel on Climate Change (IPCC) under four different representative concentration pathways (RCPs; Moss et al. 2010, Meinshausen et al. 2011). Used as the basis for this report, the RCPs are climate change scenarios based on potential greenhouse gas concentration trajectories introduced in the fifth climate change assessment report of the Intergovernmental Panel on Climate Change (IPCC 2013). The IPCC’s process-based approach for estimating future sea levels contrasts with other estimates from semi-empirical techniques that commonly generate higher numbers.

This report provides estimates of sea level change due to climate change for 118 National Park Service units and estimates of storm surge for 79 of those units. As temperature increases, sea levels rise due to a number of factors that will be discussed in greater detail. As sea levels incrementally rise, periods of flooding caused by storms and hurricanes exacerbate the growing problem of coastal inundation (see list of terms). Peek et al. (2015) estimated that the cost of sea level rise in 40 National Park Service units could exceed $40 billion if these units were exposed to one-meter of sea level rise. The aim of this report is to: 1) quantify projections of sea level rise over the next century based on the latest IPCC (2013) models, and 2) show how storm surge generated by hurricanes and extratropical storms could also affect these parks.

When Hurricane Sandy struck New York City in 2012 it caused an estimated $19 billion in damage to public and private infrastructure (Tollefson 2013). This single storm cannot be attributed to anthropogenic climate change, but the storm surge occurred over a sea whose level had risen due to climate change. Extreme storms such as Hurricane Sandy have extreme costs. When Hurricane Sandy struck it was estimated to have a return period between a 398 year (Lin et al. 2016) and a 1570 year storm (Sweet et al. 2013). Currently, a 100 year storm surge in New York City could cost $2–5 billion and a 500 year storm surge could cost $5–11 billion (Aerts et al. 2013). Under future scenarios of increasing anthropogenic greenhouse gas emissions, models project increasing storm intensities (Mann and Emanuel 2006, Knutson et al. 2010, Lin et al. 2012, Ting et al. 2015). When this change in storm intensity (and therefore, storm surge) is combined with sea level rise, we expect to see increased coastal flooding and the permanent loss of land across much of the United States coastline. Increasing sea levels increase the likelihood of another Hurricane Sandy-sized storm surge striking New York City. Factoring in future sea level rise to these estimates reduces the potential return interval of a similar storm surge occurring by 2100 to between 50 years (Sweet et al. 2013) and 90 years (Lin et al. 2016).
Format of This Report
This report contains five sections (introduction, methods, results, discussion, and conclusion), and presents results per park alphabetically by region. The 118 park units studied for this project cover six administrative regions: the Northeast, Southeast, National Capital, Intermountain, Pacific West, and Alaska. The scope of this project focuses on sea levels. The scope of this project did not include projected changes in lake levels, although interior waterways and lakes, especially the Great Lakes, are vulnerable to the effects of climate change. Further explanation on how to access the data from this project is available in the methods sections and accompanying appendices.

Frequently Used Terms
Definitions of the most basic terms used in this report occur on page ix. However, some terms require greater explanation for their use. For example, we follow the advice of Flick et al. (2012) in differentiating between the terms flooding and inundation. While many choose to use these terms interchangeably, we use the term “flooding” to describe the temporary impoundment of water on land. This usually results from storm activity and other short-lived events, such as periodic tidal action, and will therefore be used here in reference to the effects of a storm surge on land. “Inundation” is used to refer to the gradual permanent submergence of land that will occur due to sea level rise.

The terms sea level rise and sea level change are also used differently. Sea level rise refers only to rising water levels resulting from an increase in global ocean volumes. In most parts of the United States this increase in water volume will lead to increasing relative sea levels. However, in some parts of the country relative sea level is decreasing due to isostatic rebound. Figure 1 shows current sea level trends based on tide gauge records for United States that span at least 30-years of data.

For example, the Southeast Region of Alaska is experiencing a decrease in relative sea level. Alaska’s crust continues to rebound following the melting of large volumes of ice that occurred for centuries to millennia on land in the form of glaciers and ice fields. Alaska is tectonically complex with extensive faults that contribute to this crustal motion. Although the volume of ocean water in this region is increasing, the rate of sea level rise is less than the rate of isostatic rebound, resulting in a decrease in relative sea level. For this reason, we use the term “sea level change” as it includes regions that will experience a decrease in relative sea level (at least in the early part of this century) as well as those that will see increasing relative sea levels.
**Figure 1.** Sea level trends for the United States based on Zervas (2009), for all available data through 2015. Each dot represents the location of a long-term (>30 years) tide gauge station. Green dots represent stations that are experiencing the average global rate of sea level change. Stations depicted by yellow to red dots are experiencing greater than the global average (primarily driven by regional subsidence) and blue to purple dots are stations experiencing less than the global average (due to isostatic rebound or other tectonically-driven factors). Methods

This report summarizes work of a three-year project initiated in 2013, analyzing sea level change in 118 National Park Service units. Consultation with regional managers regarding units they considered to be potentially vulnerable to sea level change and/or storm surge resulted in selection of these 118 coastal park units (Appendix B). Project activities included the following:

1) Prepare sea level projections over multiple time horizons for each park unit.

2) Estimate potential exposure to storm surge using the National Oceanographic and Atmospheric Administration (NOAA) Sea, Lake, and Overland Surge from Hurricanes (SLOSH) Model and Tebaldi et al. (2012).

3) Create wayside exhibits\(^1\) with information about the impacts of climate change in the coastal zone for three National Park Service units.

Based on recommendations from regional personnel, three National Park Service units were selected as sites for wayside exhibits: Gulf Islands National Seashore, Jean Lafitte National Historical Park and Preserve, and Fire Island National Seashore. The finished wayside designs are in Appendix C. Each design is different, customized to reflect the messaging and/or themes of each unit.

Sea Level Rise Data

Sea level rise is caused by numerous factors. As human activities release CO\(_2\) and other greenhouse gases into the atmosphere, mean global temperatures increase (IPCC 2013, Gillett et al. 2013, Frolicher et al. 2014). Rising global temperatures cause ice located on land and in the sea to melt. The melting of ice found on land, such as Greenland and Antarctica, is a significant driver of sea level rise.

While the melting of sea ice is problematic from an oceanographic and heat budget perspective (primarily because it alters water temperatures and salinity and also because it changes the reflectance of solar energy from the surface), melting sea ice does not cause sea level rise. It is the melting of ice that is currently stored on land that raises global sea levels. Water level does not change when sea ice (ice wholly supported by water) melts. The volume of water in the sea remains the same whether it is frozen or liquid. The phase shift of water from solid to liquid does not displace an additional volume of water.

As ocean waters warm, the density of these waters also changes, causing thermal expansion. Thermal expansion was responsible for two-fifths of sea level rise from 1993 to 2010, while melting ice accounted for half (IPCC 2013). Table 1 lists the contribution to sea level rise from several key sources.

\(^1\) A wayside is an exhibit designed to be installed outside for visitors to learn about a particular subject (https://www.nps.gov/hfc/products/waysides/).
The IPCC sea level rise projections used in this analysis follow a process-based model approach, which estimates sea level based on the underlying physical processes. This contrasts with semi-empirical models that combine past sea level observations with other variables or theoretical considerations, including, in some cases, expert opinion (surveys or interviews of professionals) (Rahmstorf 2010, Orlic and Pasaric 2013). Often the semi-empirical approach yields higher sea level estimates. IPCC (2013) uses coupled atmosphere-ocean general circulation models (AOGCMs) to simulate the processes of change rather than the statistical inferences of the semi-empirical approach. AOGCMs are considered a process-based technique, although some variables derive from semi-empirical methods (IPCC 2013).

Sea level rise estimates for 2050 and 2100 were taken directly from the IPCC (2013) regional climate models (RCMs) downscaled to a spatial grid resolution of 1˚ x 1˚ from AOGCMs. Because many park units require estimates for shorter time horizons that fit more closely with the expected lifetime of various projects, sea level rise projections for 2030 were calculated using IPCC RCM data for each sea level rise driver shown in Table 2, interpolated to 2030 for each RCP. All projections are reported relative to the period 1986–2005 (see Appendix B for further discussion). All geographic information systems (GIS) maps display the projected sea level on top of mean higher-high water (MHHW) using the most recent tidal datum epoch (1983–2001). MHHW is calculated by averaging the highest daily water level over a 19-year tidal datum epoch.

\(^a\)Changes in ice mass derived through direct observation and satellite data.

The standard error (\(\sigma\)) for each site estimate was not calculated because it was beyond the scope of this project. However, it can be calculated using the following equation and data available from the IPCC (2013, supplementary material):

\[
\sigma_{\text{tot}}^2 = (\sigma_{\text{steric/dyn}} + \sigma_{\text{smb.a}} + \sigma_{\text{smb.g}})^2 + \sigma_{\text{glac}}^2 + \sigma_{\text{IBE}}^2 + \sigma_{\text{GIA}}^2 + \sigma_{\text{LW}}^2 + \sigma_{\text{dyn.a}}^2 + \sigma_{\text{dyn.g}}^2
\]

Where: \(\text{steric/dyn}\) = the global thermal expansion uncertainty plus dynamic sea surface height; \(\text{smb.a}\) = the Antarctic ice sheet surface mass balance uncertainty; \(\text{smb.g}\) = the Greenland ice sheet surface mass balance uncertainty; \(\text{glac}\) = glacier uncertainty; \(\text{IBE}\) = the inverse barometer effect uncertainty; \(\text{GIA}\) = global isostatic adjustment; \(\text{LW}\) = the land water uncertainty; \(\text{dyn.a}\) = Antarctica ice sheet rapid dynamics uncertainty; and, \(\text{dyn.g}\) = Greenland ice sheet rapid dynamics uncertainty.

Initial data were exported as GeoTIFF files for use in ArcGIS. For parks that crossed more than one pixel, an average sea level rise was calculated by weighting pixel values by the length of park shoreline in each pixel. A standard bathtub model approach was used to identify areas of projected inundation and flooding. In this method, projected sea level under climate change was determined by adding the IPCC RCM value to the current mean high water level. The land that would be at or below a projected sea level was then determined by analyzing digital elevation models (DEMs) of land elevation at spatial resolutions of 500 to 7000 m, depending on data availability for the areas of each park. DEM data for most regions were gathered from the NOAA digital coast website (https://coast.noaa.gov/digitalcoast). Areas of inundation and flooding are denoted in the maps (Appendix A) in blue. Additional low-lying areas that could be potentially inundated or flooded are shown in green (Figure 2). These low-lying areas do not appear to have any inlet or other pathway for water (based on our elevation datasets), although they should still be considered vulnerable to exposure to either groundwater seepage or potential flooding via breaching. The lack of high-resolution DEMs and time constraints prevented us from attempting a dynamic modeling approach (see limitations below). Maps were created to illustrate inundation for all park units for 2050 and
2100 under RCP4.5 and RCP8.5. These two represent a plausible range of scenarios between significant policy response (RCP4.5) and business as usual (RCP8.5).

---

**Figure 2.** An example of how areas of inundation appear in ArcGIS. In this example for the Toms Cove area of Assateague Island National Seashore, areas of inundation (RCP4.5 2050) appear in blue. Green shading indicates other low lying areas that are blocked from inundation by some impediment, but nonetheless could experience flooding should the physical barrier be removed or breached.

---

**Storm Surge Data**

NOAA SLOSH data estimate potential storm surge height at current (most recent tidal datum) sea level (NOAA 2016). The NOAA SLOSH model comprises the following three products (P-Surge, MEOW, and MOMs) that utilize three different modeling approaches (probabilistic, deterministic, and composite) to estimate storm surge.

P-Surge (also known as the tropical cyclone storm surge probabilities product) uses a probabilistic approach by examining past events to estimate the storm surge generated by a cyclone that is present and within 72-hours of landfall. It statistically evaluates National Hurricane Center data (calculated in part using a deterministic approach) including the official projected cyclone track and historical forecasting errors. It also incorporates astronomical tide calculations and variations in the radius of
maximum wind into this estimate. These rates of motion variables are then fit to a Cartesian or polar (depending on the location) grid (Jalesnianski et al. 1992).

The Maximum Envelope Of Water (MEOW) calculates flooding using past SLOSH output to create a composite estimate of the potential storm surge generated by a hypothetical storm. This product generates a worst-case scenario based on a hypothetical storm category that includes forward speed, trajectory of the storm when it strikes the coastline, and initial (mean vs. high) tide level that will also incorporate any historical uncertainty from previous landfall forecasts.

The final SLOSH product is the MOM (Maximum of MEOWs) model. MOM is a further composite approach that uses the forward speed, trajectory, and initial tide level data that is also used by MEOW to create a worst-of-the-worst scenario (or “perfect storm”). Storms are simulated for 32 regions (also known as operational basins, Figure 3) defined by NOAA. Data was imported into ArcGIS using the SLOSH display program. Maps were generated showing storm surge for all possible Saffir-Simpson hurricane categories for each site. While most sites had data for Saffir-Simpson hurricane categories 1–5 (Table 3), a few sites, such as Acadia National Park, were missing the highest category. NOAA did not model this scenario because it is considered extremely unlikely at a location that far north in the Atlantic Ocean.

![Figure 3. An example of the extent of an operational basin shown in NOAA’s SLOSH display program (http://www.nhc.noaa.gov/surge/slosh.php). The black area is the full extent of the operational basin for Chesapeake Bay.](image-url)

SLOSH MOM was used to estimate potential storm surge in 79 coastal park units. Unfortunately, MOM data do not exist for the remaining 39 units, so we supplemented this with data from Tebaldi et al. (2012) wherever possible. Tebaldi et al. (2012) used 55 long-term tide gauge records to calculate potential sea level and storm surge estimates above mean high water levels. We used the current 50-year and 100-yr return level data from their paper for any parks near a tide gauge. Unfortunately, due to insufficient coverage by tide gauges in this area, we were unable to use either Tebaldi et al. (2012) or SLOSH MOM data for the Alaska, Guam, and American Samoa park units. It is important to note that the Tebaldi (2012) and SLOSH MOM data differ in their methods of calculation making it inadvisable to compare storm surge values from the Pacific West Region to other regions. However, this method had to be used due to the lack of SLOSH MOM data for the Pacific West Region.

We recommend that parks planning for future hurricanes use information from one hurricane category higher than any previous storm experienced. Historical hurricane data from the International Best Track Archive for Climate Stewardship (IBTrACS; Knapp et al. 2010) is listed in Appendix D (Table D3) to allow staff to determine the highest Saffir-Simpson category hurricane to strike within 10 miles of each park unit. Applying information from one storm category higher than historical data may more closely approximate what could happen in the future, as storms are projected to be more intense under continued climate change (Emanuel 2005, Webster et al. 2005, Mendelsohn et al. 2012). However, we recommend caution in using this approach for any detailed (site-level) planning due to limitations discussed in the following section of this report.

**Limitations**
All projects of this nature have limitations that should be clearly described to ensure appropriate use and interpretation of these data.

Every effort has been made to incorporate any parks established after this project began (e.g. Harriet Tubman Underground Railroad National Monument); however, some maps might be missing due to lack of available boundary data in new units.

Sea level and storm surge estimates were derived using separate programs from the IPCC and NOAA, respectively. These numbers were then imported into GIS maps using the program ArcGIS. We used a bathtub modeling approach to map the extent of sea level rise and storm surge over every unit. Bathtub modeling simply simulates how high or how far inland water will go under different...
climate change scenarios. It does not recognize changes in topography or other environmental or artificial systems that may exist or occur in response to encroaching water. Although the bathtub model is the most widely used technique for modeling inundation, it is also a simplistic approach to simulating how sea level rise will affect a landscape (Storlazzi et al. 2013). Dynamic models could simulate changes in flow around buildings or estimate how topographic features such as dune systems may migrate in response to inundation and flooding, but dynamic models also vary, which can be a severe limitation in trying to standardize data for summary analysis and comparison.

The maps provided through this analysis vary in horizontal and vertical accuracy depending on which digital elevation model (DEM) data were available at the time of mapping. This is discussed in more detail in the metadata that accompany each map. DEM data for most regions were gathered from the NOAA digital coast website (https://coast.noaa.gov/digitalcoast/) which uses source elevation data that either meet or exceed current Federal Emergency Management mapping specifications. These NOAA digital coast data were required to have a minimum root mean square error of 18.5 cm for low lying areas that were then corrected for MHHW using the NOAA VDatum model (Parker et al. 2003). USGS data were used for areas, such as Alaska, where digital coastal data were not available. We recommend referring to Schmid et al. (2014) for further discussion on potential uncertainty of this technique.

Although SLOSH MOM has the widest geographic storm surge coverage of any model in the US, storm surge data were not available for every part of the coastline. Every effort has been made by this project to bridge any gaps where SLOSH MOM does not exist. While the Tebaldi et al. (2012) data cover the California, Oregon, Washington, and southern Alaskan coastlines, they do not cover northern Alaskan, American Samoan, or Guam coastlines. These coastlines are vulnerable to storm surge but we could not find data that satisfied our standards of accuracy sufficiently to be included in our mapping efforts.

Furthermore, storm surge maps are only intended as a rough guide of how flooding caused by storm surge will look today. As more of the coastline becomes inundated we can expect coastal flooding patterns to also change accordingly. The SLOSH model is a multiple scenario approach that uses previous storms to estimate future storm surge. It cannot take into account changes in future basin morphology that could affect the fluid dynamics and propagation of coastal flooding.

SLOSH MOM is modeled using mean sea level (0 m NAVD88) and what NOAA terms “high tide” (which is not tied to the local tidal datum, but is actually a round number based on the modeled average high tide for the region). Jalesnianski et al. (1992) estimate surge estimates to be accurate +/-20%, although Glahn et al. (2009) discuss how others have found the P-Surge model to be more accurate than originally estimated. Such factors must be kept in mind when using these numbers for mapping.

**Land Level Change**

It is important to include changes in land level while interpreting changes in sea level. The IPCC (2013) includes a limited amount of data regarding changes in relative sea level in their calculations of sea level change. Our sea level rise results include the IPCC estimates of how changes in land
level will change over time based on estimates of glacial isostatic adjustment. Land level change is an important variable when calculating relative sea level. Land levels have changed over time in response to numerous factors. Changes in various land-based loadings—such as ice sheets during the last glacial maximum—has been a significant cause of land level change in the U.S. Post-glacial isostatic rebound is the result of this pressure being released after the removal of ice sheets on the Earth’s crust. Land level can also be altered by other factors such as tectonic shifts, particularly along the Alaska and continental U.S. Pacific coastlines. These drivers can often prompt a relative increase or decrease in land level depending on location. Other factors such as aquifer drawdown and the draining of coastal swamps can create decreases in relative land level.

Quantifying how land levels are changing is difficult given the paucity of data available prior to modern satellite data. An upcoming NASA publication on land-based movement (Nerem pers. comm.) will help to address this data need, providing numbers for land-based movement across the country. Data from the NASA report can then be incorporated with sea level rise numbers from this analysis using the following equation (after Lentz et al. 2016):

$$\text{Eq. 2} \quad a_e = E_0 - e_i + R$$

Where; $a_e$ is the adjusted elevation, $E_0$ is the initial land elevation, $e_i$ is the future sea level for either 2030, 2050, or 2100, and $R$ is the current rate of land movement over time due to isostatic adjustments.

In the interim, tide gauges can provide further data regarding changes in land level, but should be used cautiously. We have listed tide gauge data for the rate of change in land level for tide gauges nearest to all units for this study in Appendix D; however, only Fort Pulaski National Monument and Golden Gate National Recreation Area have a long-term tide gauge on site. This lack of nearby long-term data can limit the accuracy of these numbers if they are applied to sea level change projections for almost all other parks units. We indicate in Table D1 which of the nearest tides gauges we do not recommend using to estimate land movement. This is because in many case the boundary of the park unit is located either too far away or on a different land mass to where the nearest tide gauge is, which increases the inaccuracy of this data. Land level changes were only reported for long-term tide gauges that had at least thirty years of data in order to ensure a statistically robust dataset. Based on these limited records, we estimate that seven park units are currently experiencing decreasing relative sea levels (Glacier Bay National Park, Glacier Bay Preserve, Katmai National Park, Kenai Fjords National Park, Lake Clark National Park, Sitka National Historical Park), although we cannot be certain of this number given that many of the park units are some distance from a tide gauge. We expect the release of the NASA data (Nerem pers. comm.) to help refine these estimates.

A discussion of the applicability of these land level numbers (with a natural resources manager or similar expert) should accompany use of individual park maps from this analysis to ensure that the nearest tide gauge to any particular project site is appropriate. Current rates of subsidence at these tide gauges range between +7.6 mm/y (Grand Isle, Louisiana) and -19 mm/y (Skagway, Alaska; Table D1). In selecting an appropriate tide gauge to use, variables including oceanographic setting, length of the record, completeness of data, and geography of the coastline must be considered. The
science team for this project decided against setting a threshold for how close a park unit should be to a long-term tide gauge based on considerations discussed above.

**Where to Access the Data**
All GIS data from this project are available at [https://irma.nps.gov/Portal](https://irma.nps.gov/Portal) for archiving by park.

A website discussing this project is available at the following address: [https://www.nps.gov/subjects/climatechange/sealevelchange.htm](https://www.nps.gov/subjects/climatechange/sealevelchange.htm)

The raw IPCC (2013) data can be downloaded using the following link: [http://www.ipcc.ch/report/ar5/wg1/docs/ar5_wg1_ch13sm_datafiles.zip](http://www.ipcc.ch/report/ar5/wg1/docs/ar5_wg1_ch13sm_datafiles.zip)
Results

Sea level and storm surge maps are in Appendix A. A full list of the 118 park units and a table listing sea level projections by park are available in Appendix D. Following the methods outlined above, we found that sea level rise projections across the 118 park units average between 0.45 m (RCP2.6) and 0.67 m (RCP8.5) by 2100. However, this number masks how these projections will vary geographically. Figure 4 shows these projections in more detail and provides sea level estimates by region. Error bars in Figure 4 denote the standard deviation for each average per region, further revealing how these numbers can vary. A high standard deviation and range signals that sea level estimates vary between units within regions, whereas a low standard deviation and small range are to be expected in smaller regions where sea level rise estimates do not cover such a large geographic area.

Figure 4. Projected future sea level by NPS region for 2100 under RCP8.5 (the “business as usual” climate change scenario). Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each region.

Based on the averages per region, we found that the shoreline within the National Capital Region is projected to experience the highest sea level rise by 2100 (0.80 m RCP8.5), although this number does not include the full extent of changes in land level over the same time interval. The shoreline near Wright Brothers National Memorial in the Southeast Region has the highest overall projected sea level rise (0.82 m, RCP8.5, 2100). Glacier Bay Preserve and Klondike Gold Rush National...
Historical Park are tied for lowest projected sea level rise at 0.33 m using RCP8.5 for 2100. The Alaska Region also has the highest standard deviation among park units. The National Capital Region conversely has very little standard deviation due to the compact nature of the region (meaning that all of the parks units fell within the same raster cell). This is not to say that all of the parks will experience exactly the same rate of sea level rise, but that the IPCC model projected that sea levels could rise up to an average 0.80 m (RCP8.5) for that region by 2100. The sea level rise maps (discussed in the National Capital section below) illustrate differences among the National Capital parks in more detail.

Comparing RCP8.5 data for 2030 and 2050 (Figures 5 and 6, respectively) shows the Northeast Region almost tied with the National Capital Region in 2030 based on average projected sea level rise, with the National Capital Region ranked highest. The Alaska Region ranks lowest for all three time intervals followed by the Pacific Northwest region, Intermountain Region, and Southeast Region. The Northeast Region ranks second highest for 2050 and 2100.

Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each region.*
Figure 6. Projected future sea level rise by NPS region for 2050 under RCP8.5 (the “business as usual” climate change scenario). Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each region.

Storm surge was mapped for 79 park units. We list data for one storm category higher than the highest historical storm in Table D3 in Appendix D. Some (31) park units did not have a historical storm path occurrence within 10 miles of their boundaries, so a Saffir-Simpson hurricane 1 was simulated for these locations. The lack of a historical storm does not mean that these parks are not subject to strong storms. It may merely be that these parks are in regions that either do not have extensive historical records or they experience strong storms, such as nor’easters, that behave differently and are not part of the NOAA database.

The Southeast Region has the strongest historical hurricanes (average of highest recorded storm categories = 2.79), followed by the Intermountain Region (average = 2.33), National Capital Region (average = 1.90), and the Northeast (average = 1.03). None of the historical data intersected with the 10-mile (16.1 km) buffers around the Alaska Region parks. The Pacific West Region has experienced some tropical depressions, particularly in Hawaii, but most of their storm surges are driven by other phenomena, such as mid-latitude cyclones or extreme tides (sometimes colloquially referred to as king tides). The strongest (highest winds) and most intense (lowest pressure at landfall) recorded historical storm to have impacted a park unit was the “Labor Day Hurricane” that passed within 10 miles of Everglades National Park in 1935. While this storm may have been the highest intensity storm, it is certainly not the most damaging or costly storm in National Park Service history.
**Northeast Region**

Colonial National Historical Park, Fort Monroe National Monument, and Petersburg National Battlefield have the highest projected sea level rise in 2050 and 2100, and, together with Edgar Allen Poe National Historic Site, Fort McHenry National Monument and Historic Shrine, Independence National Historical Park, and Thaddeus Kosciusko National Memorial (parks near coastlines) they also have the highest projected sea level rise for 2030. However, while these parks may have ranked highly, caution should be used in applying these results. Many of these parks do not have coastline and so these projections are based on sea level rise for the coastline adjacent to these parks. The maps in Appendix A show how the projected sea level rise may affect each of these parks. Colonial National Historical Park, Fort McHenry, and Fort Monroe National Monument are the only park units of this highest rise grouping that contain coastline with their boundaries.

Figure 7 shows the range of sea level projections for the Northeast Region for 2100, averaging between 0.49 m (RCP2.6) and 0.74 m (RCP8.5) of sea level rise by the end of the century. Acadia National Park had the lowest projected rates of sea level rise for 2030 (0.08–0.10 m), 2050 (0.14–0.19 m), and 2100 (0.28–0.54 m).

![Figure 7](image_url)

**Figure 7.** Projected future sea level rise by 2100 for the NPS Northeast Region under all of the representative concentration pathways. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each category.
Regarding storm surge, the highest recorded storm to have travelled within 10 miles of any of the 29 parks units identified for study was an officially unnamed hurricane in 1869 known colloquially as Saxby’s Gale, which was classified as a Saffir-Simpson 3 hurricane. The storm path passed present-day Boston National Historical Park and Roger Williams National Memorial. Figure 8 shows the estimated extent and height of a storm surge from category 3 hurricane striking Boston Harbor Islands National Recreation Area at mean tide.

![Figure 8. Estimated storm surge created by Saffir-Simpson category 3 hurricane occurring at high tide near Boston Harbor Islands National Recreation Area. Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range).](image)

**Southeast Region**
Historically, the Southeast Region has the highest intensity storms (highest Saffir-Simpson storm category); Everglades National Park has recorded a category 5 hurricane within 10 miles of its boundary, the colored areas in Figure 9 indicate the potential height and extent of a storm generated by two different categories of hurricane. A category 2 hurricane could completely flood the park.

Future storm surges will be exacerbated by future sea level rise nationwide; this could be especially dangerous for the Southeast Region where they already experience hurricane-strength storms.
Moreover, sea level rise projections only include changes in land movement due to glacial isostatic adjustment and do not include the full range of drivers of potential changes in land level. Using Table D1 from Appendix D as a rough guide, changing land level for parks near tide gauges can be evaluated. For example, the Eugene Island, Louisiana tide gauge’s current rate of sea level rise is the highest in the country at 9.65 mm/y, owing in part to the large rate of subsidence in the region (Figure 1). Using the nearest tide gauge to Jean Lafitte National Historical Park and Preserve (Grand Isle, Louisiana, gauge 8761724) we can estimate that land will subside by 7.60 mm/y. Applying this estimate of subsidence (using a baseline of 1992) to our RCP8.5 projections, the park could experience approximately 0.41 m of relative sea level rise by 2030 followed by 0.69 m by 2050 and 1.50 m by 2100. This is an inexact estimate of the land movement for the park given that Jean Lafitte National Historical Park and Preserve is approximately 60 miles (97 km) from the tide gauge; still, factoring in changes in land level, we can see that relative change in sea level is more than double the projected change in sea level using the IPCC estimates alone.

This analysis projects that, by 2100, the shoreline adjacent to Wright Brothers National Memorial may have the greatest sea level rise among the Southeast Region’s parks (0.82 m RCP8.5). Given elevations within the park, this may not inundate a large area of the memorial, unless combined with other factors such as a storm surge. For example, the park may be almost completely flooded if a category 2 or higher hurricane strikes on top of inundation from sea level rise.

Nearby Cape Hatteras and Cape Lookout National Seashores are projected to experience sea level rise of up to 0.79 m and 0.76 m, respectively (RCP8.5) by 2100, resulting in large areas of inundation. While sea level rise around these national seashores may not be as high as what has been projected for Wright Brothers National Memorial, they serve as examples of how caution must be used when using these numbers to assess which park units are most vulnerable to sea level rise. Other factors, such as percent of exposed land, changes in land movement, and adaptive capacity must also be taken into account for vulnerability analyses (Peek et al. 2015).
Figure 9. SLOSH MOM storm surge maps for a Saffir-Simpson category 1 (left) versus category 2 hurricane striking Everglades National Park at mean tide (right). Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range).
National Capital

National Capital Region has minimal variability in projected sea level rise because all park units selected for study are adjacent to the same section of coastline that was modeled. Their proximity also explains why they share the same storm history. Despite these similarities, projected sea level rise may affect each individual park unit differently based on local topography. The strongest storm recorded within 10 miles (10.1 km) of the National Capital Region parks was a Saffir-Simpson category 2 hurricane that struck the city in 1878. While the 1878 storm caused relatively little damage, we can expect a significantly larger amount of damage if a similar storm struck the city again given considerable development now existing in the area. Figure 10 shows the extent of flooding caused by a Saffir-Simpson category 2 hurricane. A storm surge measuring more than 3 m could travel up the Potomac River causing large amounts of flooding. Such a storm surge could be worse by the end of this century given projected sea level rise around the Capital Region of up to 0.8 m.

Figure 10. A SLOSH MOM map showing storm surge height and extent created by a Saffir-Simpson category 2 hurricane striking the Washington D.C. region at high tide. Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range).
IPCC/SLOSH models showed either storm surge or sea level rise (or some combination of the two) affecting every National Capital Region park included in this analysis, with the exception of Harpers Ferry National Historical Park. Our mapping efforts revealed that Harpers Ferry National Historical Park (located approximately 149 m above sea level) is unlikely to experience any impacts of sea level rise due to its elevation and is unlikely to be damaged by storm surge from a hurricane, given its relatively protected location behind several dams along the Potomac and Shenandoah Rivers.

Sea level rise alone is not expected to spread very far into Washington D.C., although a large section on the east side of Theodore Roosevelt Island could be inundated. However, storm surge flooding on top of this sea level rise would have widespread impacts.

**Intermountain Region**

The Intermountain Region covers mostly inland park units stretching from Texas to Montana. Within the region, only three park units in Texas are subject to sea level change: Big Thicket National Preserve, Palo Alto Battlefield National Historical Park, and Padre Island National Seashore. Of these, Padre Island National Seashore may experience the greatest effects of sea level and storm surge; sea level is projected to rise 0.46–0.69 m (RCP2.6–8.5, Figure 11) by 2100. The same amount of sea level rise is projected for the shoreline near Palo Alto Battlefield National Historical Park, but inundation is not projected to extend far enough to reach the park. Palo Alto Battlefield National Historical Park has no history of being within 10 miles of any hurricane, making the site unlikely to be flooded by storm surge. SLOSH MOM models for the park unit show that the region would have to have either a Saffir-Simpson category 4 hurricane striking at high tide or a category 5 hurricane striking at any tide in order for the park to experience any storm surge. On the other hand, Figure 12 shows that Padre Island National Seashore, located to the east of Palo Alto Battlefield National Historical Park, historically was within 10 miles of a category 4 hurricane. SLOSH MOM data show that should a category 4 hurricane occur here again, it would likely flood almost the entire island.

Storm surge could potentially travel up the Neches River and flood the southernmost part of Big Thicket National Preserve, although both artificial and natural storm surge defenses in Beaumont, Texas, to the south of the preserve, may buffer it from any surge.
Figure 11. Projected future sea level rise by 2100 for the NPS Intermountain Region under all of the representative concentration pathways. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation from each mean. Blue bars mark the full range of sea level estimates for each category.
Figure 12. A SLOSH MOM map showing storm surge height and extent created by a Saffir-Simpson category 4 hurricane striking the southwestern Texas region at mean tide. The dark green line around the island represents the boundary of Padre Island National Seashore. Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range).
**Pacific West Region**
The Pacific West Region identified 24 park units for analysis in this study that could be vulnerable to sea level rise and/or storm surge. These units occur over a large area that includes California, Oregon, Washington, Hawaii, American Samoa, and Guam. War in the Pacific National Historical Park in Guam has the highest projected sea level rise at 0.68 m (RCP8.5) by 2100, and shares the highest projected sea level rise with almost all of the Hawaiian park units in 2030 and 2050. The average projected sea level rise range is 0.40–0.58 m (RCP2.6–8.5) by 2100 for the whole region; high standard deviations (0.04 m and 0.08 m for RCP2.6 and RCP8.5, respectively) indicate that park-specific projections vary widely across the region.

At the other end of the spectrum, projected sea level rise around Washington’s Olympic Peninsula and in the San Juan Islands, affecting Ebey’s Landing National Historical Reserve, Olympic National Park, and San Juan Island Historical Park, is expected to occur more slowly, reaching a maximum 0.46 m (RCP8.5) by 2100. This region is subject to tectonic shifts and continuing land movement due to isostatic rebound, further complicating sea level projections. Long-term tide gauge records at Neah Bay, Washington (gauge 9443090), and Tofino, British Columbia, Canada (gauge 822-116), show relative sea levels currently decreasing while tide gauges in Port Angeles, Washington (gauge 9444090), Victoria, Canada (gauge 822-101), and Seattle, Washington (gauge 9447130), show it to be increasing (Zervas 2009). Our projections indicate rising sea level in this region throughout this century, although further investigation of localized changes in land movement could shed more light on this matter.

Park units in the Pacific West Region need to be concerned about potential future storms that could travel along the eastern Pacific Ocean’s increasingly warmer waters. Because of the relative lack of hurricanes in this region historically, we used data from Tebaldi et al. (2012), which includes anomalous surges that could be created by storms, and other factors (very high tides sometimes referred to as king tides). Based on the Tebaldi et al. (2012) data, La Jolla, California (gauge 9410230), has the lowest 100-year storm surge (0.95 m) and Toke Point, Washington (gauge 9440910), has the highest 100-year storm surge (1.96 m) in the Pacific West Region. Tebaldi et al. (2012) did not analyze storm data for Hawaii, Guam, or American Samoa, although IBTrACS (Knapp et al. 2010) does have hurricane records for these areas. Only tropical depressions have been recorded within 10 miles of almost all of the Hawaiian park units we analyzed (Haleakala National Park, Hawaii Volcanoes National Park, Kalaupapa National Historical Park, Kaloko-Honokohau National Historical Park, Puukohola Heiau National Historic Site, and World War II Valor in the Pacific National Monument).

**Alaska Region**
The Alaska Region has the lowest average projected sea level rise (0.28–0.43 m by 2100) compared to the five regions described above. Glacier Bay National Park and Preserve and Klondike Gold Rush National Historical Park in southeastern Alaska share the lowest projected sea level rise (0.33 m, RCP8.5, 2100) while Bering Land Bridge National Preserve on the west coast of the state has the highest projected sea level rise (0.60 m, RCP8.5, 2100).
Figure 1 shows how current relative sea levels vary across the state. Land levels are rapidly rising in the southeast of the region due to isostatic rebound and other tectonic shifts. The net result of these increasing land levels is decreasing relative sea levels for at least the early part of this century. Relative sea level in Skagway, Alaska is decreasing at an average rate of 17.6 mm/y (Zervas 2009). Despite melting ice and other factors outlined in Table 1 that increase ocean water volume, the amount of rising water is insufficient to keep up with land level changes. Seven park units (Glacier Bay National Park, Glacier Bay National Preserve, Katmai National Park, Kenai Fjords National Park, Lake Clark National Park, Sitka National Historical Park) are identified as potentially having decreasing relative sea levels based on the nearest tide gauge data to each of these parks. None of these parks have long-term tide gauges with data spanning at least thirty years. A great strength of using the IPCC (2013) process-based model approach is that, unlike many other semi-empirical models, it does not rely on long-term tide gauge records to statistically project future sea levels. However, sea level projections in this analysis do not include changes in land level. The estimates that we report here represent the expected rise due to water volume expansion alone near to each of these park units. Table D1 shows how land levels are changing at long-term tide gauges across the country. However, given that all of these park units are located far from a tide gauge and that the region is relatively geologically complex, we do not recommend using the land movement numbers from the nearest tide gauge for any of the Alaskan parks.

Storm surge is also very difficult to model for this region. Historically, many of the parks had sea ice along the coastline that helped protect these parks from storm surge. Consequently, NOAA does not have SLOSH MOM models for this region. IBTrACS data (Knapp et al. 2010) show a few storm paths that have moved towards the region, but these types of storms typically do not make landfall once they move over colder waters. Alaska does hold the record for the highest intensity (lowest central pressure) storm (Duff 2015). A downgraded super typhoon, Nuri, struck Adak Island, Alaska, in 2014 with recorded winds gusting up to 122 mph. It is impossible to determine an average or peak historical storm surge without adequate tide gauge data.
Discussion

Global mean sea levels have been rising since the last glacial maximum (Lambeck and Chappell 2001, Clark and Mix 2002, Lambeck et al. 2014). Church and White (2006) estimated that twentieth century global sea levels rose at a rate of approximately 1.7 mm/y, although this rate accelerated over the latter part of the century. Slangen et al. (2016) found that emissions of greenhouse gases from human activities have been the primary driver of global sea level change since 1970 and that the rate of sea level rise has increased over time (Table 1). Satellite altimetry data shows that present-day global relative sea levels are increasing at approximately 3.3 mm/y (Cazenave et al. 2014, Fasullo et al. 2016).

The IPCC (2013) projects that, without greenhouse gas emissions reductions, this rate will increase, and that global average sea levels could rise by 0.40–0.63 m (RCP2.6–8.5) by 2100. We used regional sea level projections from the IPCC (2013) generated for 2050 and 2100 in combination with our interpolated projections for 2030 to estimate the amount of sea level rise 118 coastal national park units could experience in the future. Our projections are based on the new representative concentration pathways (Moss et al. 2010, Figure 13), using a process-based model approach.

![Figure 13](image)

*Figure 13. Radiative forcing for each of the Representative Concentration Pathways (RCPs). An increase in radiative forcing (due to the loading of anthropogenic gases into the atmosphere) will result in higher global average temperatures. RCPs replace the IPCC SRES scenarios. Note how RCP4.5 (yellow line) projections are slightly higher than RCP6.0 (gray line) in the early part of this century. Source: Meinshausen et al. 2011.*
Numerous academic articles use mostly semi-empirical models (Rahmstorf 2007) to estimate sea level rise regions across the U.S. The IPCC (2013) lists several semi-empirical sea level rise estimates, all of which result in projections of future sea level that are higher than the IPCC (2013) approach. The differences in these approaches can be attributed to many factors. For example, some of the older papers may have higher sea level estimates because they are based on the older IPCC SRES scenarios (e.g. Vermeer and Rahmstorf 2009, Grinsted et al. 2010, Jevrejeva et al. 2010). Other papers may include input from “expert elicitations” in their sea level projections, in which experts provide their opinion on how much sea level (or a related factor) could rise in the future (e.g. Bamber and Aspinall 2013, Jevrejeva et al. 2014, Horton et al. 2014). Some published articles criticize the IPCC sea level estimates as being too conservative or underestimating rates of future sea level change (e.g. Kerr 2013, Horton et al. 2014). Church et al. (2013) addresses these criticisms by explaining how the IPCC define the probability and likelihood of their estimates, and so they are not discussed in detail here. Recent analyses by Clark et al. (2015) further support the findings of the IPCC.

A key strength of the methods used in this analysis lies in providing a unified approach to identify how sea level change may affect all coastal park units across the National Park System, rather than relying on sea level data generated for specific areas. Our analyses revealed that the National Capital Region is projected to experience the greatest increase in sea level (not taking into account changes in land level). This rise will affect each of the region’s units in different ways depending on the elevation of the individual unit, but it could be significant if combined with a storm surge from a storm such as the Saffir-Simpson category 2 hurricane in 1878.

At the individual park level, IPCC projections reveal the sea level along the coastline adjacent to Wright Brothers National Memorial could rise up 0.82 m (RCP8.5) by 2100, which could lead to significant flooding if the dynamic landforms are not able to keep pace with such high rates of sea level rise. In addition, storm surge impacts at this higher sea level would be significant. The Southeast Region as a whole is generally susceptible to inundation and flooding due to its low-lying nature in many places, particularly in Cape Hatteras and Cape Lookout National Seashores. Our sea level rise maps (Appendix A) highlight how much all of these park units may be affected.

These estimates do not include the latest data on changing land levels. The IPCC included estimates of global isostatic adjustment (Equation 1) in their predictions, but those do not include changes in land level due to other factors, such as earthquakes and groundwater extraction. We expect the latest, state-of-the-art land level estimates to be released by NASA in 2017. In the meantime, we can roughly estimate relative sea level change for a small number of parks based on current rates of subsidence gathered from nearby long-term tide gauge data. We project Jean Lafitte National Historical Park and Preserve to have the greatest relative sea level increase based on the current rate of land movement. Our sea level projections agree with current sea level trends in showing that the southeast Alaska region is experiencing the least amount of sea level rise of anywhere in the National Park System.
Sallenger et al. (2012) discussed how changes in Atlantic Ocean temperatures and salinity (resulting from changes in circulation) could lead to changes in sea level that could create a 1000-km long “hotspot” along the North Atlantic coast from Cape Cod, Massachusetts to Cape Hatteras, North Carolina. We estimate that almost all of the coastal park units in this area would be flooded under these conditions.

It is unknown exactly to what degree future storm surge will affect the Alaskan park units. Accurate long-term (>30 years) storm surge data do not exist for the Alaska region. Even if such data did exist, it would be not be analogous to future conditions in the region because sea ice that had previously protected the shores for many of the western Alaska park units melts to reveal an easily erodible coastline (Frey et al. 2015). The warming of ocean waters in the Gulf of Alaska and Pacific Ocean could also make it more conducive for more storms like Typhoon Nuri to travel north without losing energy as under historic conditions.

The Pacific West Region shows high variability among parks. War in The Pacific National Historical Park in Guam ranks highest in projected sea level rise among units in the Pacific West Region. The large area of the region partly explains the relatively high standard deviation in results for the region. The tectonically complex setting of many of the region’s parks also complicates future sea level estimates. Changes in land movement are somewhat gradual nationwide in comparison to Alaska and the Pacific West Region, especially where earthquakes can rapidly change the position of the land relative to the sea.

Island park units in general are particularly exposed to the impacts of sea level change and storm surge. Many of the barrier island parks, such as Fire Island National Seashore, Assateague Island National Seashore, Palo Alto Battlefield National Historical Park, Gulf Islands National Seashore, and Cape Hatteras National Seashore, are all projected to experience sea level rise of over 0.69 m by 2100 (RCP8.5). This sea level rise, combined with storm surge, could be especially difficult for isolated island park units, such as the Caribbean park units, the National Park of American Samoa, and War in the Pacific National Historical Park, where access to aid in the event of a natural disaster may not be immediately available.
Conclusions

This report presents projections of sea level change (118 parks) and storm surge (79 parks) in coastal park units administered by the National Park Service. Sea level change and storm surge vary geographically, resulting in locally-specific challenges for adaptation and management. It is important to acknowledge that sea level change will affect some parts of Alaska differently than coastal parks in the rest of the country. Northwest Alaska can expect relative sea levels to increase over time; while in southeast Alaska, relative sea levels may continue to decrease over the first part of this century, followed by an increase in relative sea level towards the end of the century.

This project is an important first step in assessing how changes in sea level and storm surge may affect national park units. Using sea level rise and storm surge information, parks can begin to plan for effects on resources, facilities, access, and other areas of management. While methods used here are not appropriate for combining the separate sea level rise and storm surge results, parks should be aware of the potential for synergistic effects of sea level rise and storm surge causing impacts larger than either may cause individually. It is clear that more research can be done on these complex issues to assess how these changes may affect parks and regions. These data can inform future projects related to both natural and cultural resources as well as the planning and management of infrastructure.

Links to Data Sources
Maps were created for this project using NOAA DEM data. For further information regarding our methods refer to methods section on page 3.

Digital versions of our sea level rise maps will be available at www.irma.gov

Storm surge maps are also available on www.irma.gov and www.flickr.com/photos/125040673@N03/albums/with/72157645643578558
Appendix B

Frequently Asked Questions

Q. How were the parks in this project selected?
A. Parks were selected after consultation with regional managers. Regional managers were given a list of parks that authors considered to be vulnerable to sea level change and/or storm surge. This list was vetted by regional managers and their staff who added or subtracted park names based on their knowledge of the region.

Q. Who originally identified which park units should be used in this study?
A. The initial list of parks was approved by the following regional managers: Northeast Region, Amanda Babson (signed 11/27/13); Southeast Region, Shawn Benge (signed 11/14/13); National Capital Region, Perry Wheelock (signed 3/17/14); Intermountain Region, Patrick Malone signed on behalf of Tammy Whittington (signed 11/13/13); Pacific West Region, Jay Goldsmith (signed 11/26/13); Alaska Region, Robert Winfree (signed 11/15/13).

Q. What’s the timeline of this project?
A. This is the culmination of a three-year project that was proposed in February 2012. Initial Fiscal year of funding was 2013.

Q. In what instance did you use data from Tebaldi et al. (2012)?
A. NOAA’s Sea Lake and Overland Surge from Hurricanes (SLOSH) model does not include storm surge predictions for all of the parks used in this study. We used data from Tebaldi et al. (2012) where reasonable to provide data for park units in California, Oregon, Washington, and southern Alaska. The following parks used Tebaldi et al. (2012) data: Cabrillo National Monument, Channel Islands National Park, Eeyou’s Landing National Historical Reserve, Fort Point National Historic Site, Fort Vancouver National Historic Site, Golden Gate National Recreation Area, Klondike Gold Rush National Historical Park, Lewis and Clark National Historical Park, Olympic National Park, Port Chicago Naval Magazine National Scenic Trail, Point Reyes National Seashore, Redwood National Park, Rosie the Riveter WWII Home Front National Historical Park, San Francisco Maritime National Historical Park, San Juan Island National Historical Park, and Santa Monica Mountains National Recreation Area.

Q. Why don’t all of the parks have storm surge maps?
A. Unfortunately some parks do not have enough data to complete a storm surge map. These were parks that were not modeled by NOAA’s SLOSH MOM model or near any of the tide gauges used by Tebaldi et al. (2012). These parks are: Aniakchak Preserve, Bering Land Bridge National Preserve, Cape Krusenstern National Monument, Glacier Bay National Park and Preserve, Katmai National Park, Kenai Fjords National Park, Lake Clark National Park, Sitka National Historical Park, War in the Pacific National Historical Park, and Wrangell – St. Elias National Park and Preserve.
Q. My park only has storm surge maps covering a few Saffir-Simpson categories. Why is that?
   A. Some parks, particularly those in the Northeast Region, were not modeled by NOAA for the full range of Saffir-Simpson storm scenarios. This is because it is considered very unlikely that a Saffir-Simpson category 4 or 5 hurricane would be able to sustain itself into the northern latitudes of that region.

Q. Why are the storm surge maps in NAVD88?
   A. That is the default datum for SLOSH data. This was a decision made by NOAA.

Q. What are the effects of NAVD88 on sea level and storm surge projections for some parks?
   A. The North American Vertical Datum of 1988 (NAVD88) is a datum that is commonly used in North America to refer to the “elevation” of a location. It uses a fixed value for the height of North America’s mean sea level. While this is a popular datum for mapping, it has the limitation that it is based on the observed mean sea level for a single location: Rimouski, Canada. As you move further away from this location you can expect actual sea level to differ from the mean sea level at Rimouski. For locations such as California this can result in a significant difference between observed mean sea level and NAVD88. Your natural resource or GIS specialist will likely have further information about your specific location. Alternatively you can look up the differences in your region by checking the datum information for your nearest tide gauge station: https://tidesandcurrents.noaa.gov/stations.html?type=Datums

Q. Which sea level change or storm surge scenario would you recommend I use?
   A. All parks are different, as are all projects. Your choice of scenario may depend on many different factors including risk tolerance and expected time horizon of the project. The NPS has not yet released any guidance on which climate change scenarios to use for planning. We would recommend you contact the appropriate project lead, natural or cultural resource manager, or someone from the Climate Change Response Program for further guidance depending on your situation.

Q. How accurate are these numbers?
   A. The accuracy of these data varies depending on the data source. SLOSH data has +/- 20% accuracy, although this is discussed in greater detail by Glahn et al. (2009). Further information about storm surge data generated by Tebaldi et al. can be found in Tebaladi et al. (2012). IPCC global sea level rise projections range between 0.26 m (RCP2.6 minimum likely range) and 0.82 m (RCP8.5 maximum likely range) by 2100. The standard error of the IPCC is explained in greater detail in the Chapter 13 supplementary material in AR5 (IPCC 2013). An explanation on the horizontal and vertical accuracy of the digital elevation models used for mapping can be found in the metadata that accompanies the map data on www.irma.gov. DEM data were required to have a \( \leq 18.5 \) cm root mean square error vertical accuracy before they were converted to MHHW. An exception to this was in Alaska where these data were not available.
Q. We have had higher/lower storm surge numbers in the past. Why?

A. The numbers given here are meant to represent a maximum based on a typical storm surge category. As described above, there is likely to be some deviation around that number. Certain periods are also likely to result in higher than average storm surges. For example, periodic changes in regional water temperatures (caused by phenomena such as El Niño and La Niña) will impact water levels that will add to any storm surge. Likewise, changes in the North Atlantic Oscillation and Pacific Decadal Oscillation will also affect ocean conditions. This must be taken into account when using these numbers. All of these factors vary temporally and geographically, so contact your natural resource manager if you are unsure how this could impact your particular park unit.

Q. What other factors should I consider when looking at these numbers?

A. These projections do not include the impact of all man-made structures, such as flood barriers, levees, and dams. They also do not take into account how smaller features, such as dune systems or vegetation changes could impact coastal flooding. There are many meso- and micro-scale factors that need to be taken into account such as differences in topography, the presence/absence of any wetlands etc. It should also be expected that as sea levels change, areas of the shoreline will change accordingly, particularly due to erosion and accretion.

Q. Why don’t you recommend that I add storm surge numbers on top of the sea level change numbers?

A. Higher sea level and permanent inundation will change the way waves propagate within a basin. Sea level change is expected to have a significant impact on the geomorphology of the coastline. Changing water levels will lead to areas of greater erosion in some areas as well as increasing accretion in other places. As sea level changes, the fluid dynamics of a particular region will also change. This is not something NOAA takes into account in their SLOSH model.

Q. Where can I get more information about the sea level models used in this study?

Q. Where can I get more information about the NOAA SLOSH model?

A. http://www.nhc.noaa.gov/surge/slosh.php

Q. So, based on your maps, can I assume that my location will stay dry in the future?

A. No. As explained above, these numbers are accurate within a certain range. Also, these maps are based on “bathtub” models where water is simulated as rising over a static surface. In reality, your coastline will change in response to storms and other coastal dynamics. These numbers are intended for guidance only.
Q. Why do you use the period 1986–2005 as a baseline for your sea level rise projections?
   A. We are following the standard approach used by the IPCC, USACE, and much of the academic literature. If you would like your estimate to start from a specific year you can do one of two things: 1) subtract the observed rate of sea level rise since 1992 for your location, or 2) contact park, region, or Climate Change Response Program staff for assistance. It may be possible to interpolate projections further to estimate the amount of rise the models estimate to have taken place between the baseline and whichever year you choose. We must caution that if you follow option 1 you will be introducing some inaccuracy to sea level projections, especially if you use data from a tide gauge that is not close to your location.

Q. The SLOSH/IPCC projections seem lower/higher than X source I’ve found. Why is that?
   A. Projections can vary depending on a number of factors such as choice of model, approach, or the age of the study. We would recommend that you speak to a climate specialist when choosing sources.

Q. What are other impacts from sea level rise that parks should consider?
   A. Impacts from sea level rise could include, but are not limited to, increased erosion, damaged cultural resources, damage to above and below ground infrastructure, difficulty accessing inundated infrastructure, increased groundwater intrusion, altered groundwater salinity, diminished space for recreational activities (possibly leading to conflict between different recreational users), and the complete loss or migration of certain coastal ecosystems. For more information on the topic, please see the Coastal Adaptation Strategies Handbook at: http://www.nps.gov/subjects/climatechange/coastalhandbook.htm
Appendix C

Waysides

The following pages show the final designs for waysides that were installed in parks as part of the funding for this project. Gulf Islands National Seashore received two waysides that were received in 2015. Jean Lafitte National Historical Park and Preserve and Fire Island National Seashores waysides were installed in 2016.
See Change...

The earth's climate is changing, raising sea level and increasing the frequency of storm surges. Erosion and rising sea level change the shape and size of barrier islands and mainland shorelines along the Gulf Coast.

The roots of coastal plants slow erosion by anchoring the land. As sea level rises, increased salt content in the soil will kill the plants leaving the land exposed to more erosion. In many places, the amount of dry land is decreasing at a significant rate.

The Gulf Coast draws millions of visitors to relax in the bright sun, play in the crystal blue surf, explore the snow white beaches, and watch for wildlife. Yet, this dry land, at the edge of rising waters, could be claimed by the Gulf of Mexico forever.

Gulf Islands National Seashore is investing in energy efficient equipment and seeking new sustainable solutions to help keep these shores from disappearing beneath the rising sea.

Each year, crocs, storms, coastal development, and rising sea level shrunk the nesting beach habitat of sea turtles. When a female sea turtle is ready to lay her eggs, she will try to return to the same sandy beach every two to three years. Will her nesting home still be here?

Please join the National Park Service in protecting these beaches so that you and your children may watch her hatchlings return to lay their eggs.

This road at Fort Pickens gets overwhelmed with storm waves. As the sea level rises, these events are becoming more common.
See Change...

The earth's climate is changing, raising sea level and increasing the frequency of storm surges. Erosion and rising sea level change the shape and size of barrier islands and mainland shorelines along the Gulf Coast.

The roots of coastal plants slow erosion by anchoring the land. As sea level rises, increased salt content in the soil will kill the plants leaving the land exposed to more erosion. In many places, the amount of dry land is decreasing at a significant rate.

Fighting the Rising Sea

Each year, erosion, storms, shipping channels, and rising sea level are changing the shoreline of the barrier islands. The National Park Service and Corps of Engineers work together on renourishment projects to rebuild the coastline around historic Fort Massachusetts. The fort is often battered by waves, putting the structure in jeopardy.

Please join the National Park Service in protecting our seashore, so that you and your children may continue to enjoy these historic places.

The Gulf Coast draws millions of visitors to relax in the bright sun, play in the crystal blue surf, explore the historic forts, and watch for wildlife. Yet, this dry land, at the edge of rising waters, could be claimed by the Gulf of Mexico forever.

Gulf Islands National Seashore is investing in energy efficient equipment and seeking new sustainable solutions to help keep these shores from disappearing beneath the rising sea.
Sinking Land, Rising Water

This is the Barataria Basin, built of soil washed to this area by the Mississippi River. This soil is still compactioning and sinking, a process called subsidence. Most of the Barataria Preserve is less than two feet above sea level, and its subsidence rate is nearly half an inch a year.

Meanwhile, glaciers and polar ice sheets are melting and our warming climate is heating oceans everywhere, making their waters expand just like water does when you heat it on the stove. Everywhere on the planet, the oceans are a little higher every day.

The combination of the Barataria Basin’s sinking land and global sea level rise means that the ocean is creepig in faster here than almost anywhere else in North America.

- Floods are becoming more frequent and lasting longer
- Coastal wetlands are disappearing as land sinks and water rises
- Less land is available to buffer Gulf of Mexico storms
- Storm and flooding threats to homes, communities, and infrastructure like highways, ports, and energy facilities are increasing
- Salt water from the Gulf is moving into freshwater wetlands, killing the plants that hold the land together
- Death of plants, animals, and microbes that cannot tolerate increased flooding or salt water
See Change In A Changing Climate

Natural landscape change can be nearly imperceptible on a barrier island, as the wind and waves gradually shape the shoreline, beach, and dunes. Natural changes can also be obvious and happen quickly during storms like hurricanes and nor’easters. Looking ahead, storms will have a greater impact on Fire Island due to climate change.

When we burn fossil fuels, carbon dioxide is released into the atmosphere and acts like a heat trapping blanket around our planet. Heat that would normally escape from the atmosphere is retained, warming the Earth, and changing climate patterns. As ocean waters warm and ice on land melts, sea level rises and impacts Fire Island and coastlines all over the world. The future of this barrier island is in jeopardy due to these human-induced climate change effects.

Fire Island protects mainland Long Island against storms and is a stunning setting for recreation, education, and inspiration. It also provides critical habitat for plants and wildlife. We must do what we can to protect this special place. By using renewable energy sources and reducing our dependence on fossil fuels, we can take steps today to preserve barrier island systems and processes, and help build natural resilience to future storms and sea-level rise.

Storm Stories

On October 29, 2012 Hurricane Sandy struck Fire Island National Seashore and changed the lay of the land. During the storm high water and large waves washed sand from the beach and dunes, moved sand across the width of the island, and carved new beaches, pictured here, through the barrier island. The storm was the strongest in recorded history to make landfall in this region.

To learn more about how climate change is impacting the Seashore, please visit www.nps.gov/fis/learn/climatechange.htm

NPS 999/137852, April 2017
I can do this when I am online tomorrow. Thank you for the offer of assistance!

Sent from my Verizon Wireless 4G LTE smartphone

-------- Original message --------
From: "Gross, John" <john_gross@nps.gov>
Date: 05/23/2017 2:16 PM (GMT-07:00)
To: Rebecca Beavers <rebecca_beavers@nps.gov>
Subject: Re: Sea Level Rise Report Final Layout Policy Review

Rebecca,

Do you want me to go ahead and activate the record, but set it for NPS-only access? The
would restrict access to the pdf, but I think anyone would be able to see the abstract and
associated metadata.

johng

wrote:

For future reference, obtaining a report number should be one of the
very last things that you do.

With our database, we have no way to get "early" report numbers.

The official publication date for that report number is tied to the exact
time and date that we give the report a new report number.

Thanks.

Fagan:

1) We do not have DOI approval to make the report public at this point. It will be internal only access for a while.

This is concerning your report that we approved for final publication on April 24, 2017.

**We need someone to do the following over the next 3-5 work days:**

1) Activate (make public) the Data Store record ([https://irma.nps.gov/DataStore/Reference/Profile/2239974](https://irma.nps.gov/DataStore/Reference/Profile/2239974)).

2) Upload the final PDF to the activated Data Store record.

Please let me know if you cannot do this yourself, and we will export the last copy that we sent back to you to create an absolute final PDF on this end.

Edits are locked once the final PDF has been made public.

On Fri, Apr 21, 2017 at 4:23 PM, Johnson, Chalmers-Fagan <fagan_johnson@nps.gov> wrote:

Hello Rebecca, everyone. Hopefully this will only require a few more minutes of your time.

The only reason that this email is long, is to provide additional guidance for what you still need to do (the three steps below), and details about exactly what I changed in your document (optional reading below the three steps).

Three Remaining Steps
(Download detailed instructions for all three steps)

Step 1. Download the updated MS Word file and final and updated MSF at:

https://drive.google.com/drive
/folders/0Bx0uAOormwkIMkYtLTU3M0pUdDQ?usp=sharing

**Maintaining your own copy of the final MSF is optional. We maintain multiple archived versions.

Step 2. Double-check and approve my updates and have Fagan export the final to PDF (Rebecca and Fagan).

a) Make your absolute final edits (if any), and send the VERY FINAL version of the .docx file back to Fagan.

If you want to know exactly what we updated in your report (optional), proceed to the ***Report Updates and Changes section below.

Make sure that there are no more changes when you send the report to Fagan. The sub-step below takes about 2-3 minutes per page. Changes after that point usually require starting over with the entire process (re-tagging all pages and not just the ones with changes).

b) When all edits are final, Fagan will export the final to
PDF format and manually check fix the HTML-type tags on each page to meet current Section 508 of the Rehabilitation Act standards, such that the final document to be read aloud correctly by special screen readers for the visually and cognitively impaired.

Step 3. Activate the draft IRMA record that I created for you, and upload the final PDF (Fagan).

a) Go to this address to open the draft Data Store record that I created for you:

https://irma.nps.gov/DataStore/Reference/Profile/2239974

b) Click the Actions drop down menu near the top right of the screen and click Edit and update the Core and Subjects and Keywords information as you desire

Note: The Data Store search engine only searches on the bibliographic information you enter here. It does not search anything located inside any uploaded digital files.

c) When you are finished updating the Data Store bibliographic information, click the Activate button at the bottom-right of the page to save your changes and make the record visible to the public.

d) Go to the Files and Links tab. On the Add drop down menu, choose the Digital File. Use the file upload tools to upload the final PDF and Activate it (the PDF Holding also has to be Active to be downloadable).

(* Download detailed instructions for all three steps*)

***Everything below this point is just for people that really want to know EXACTLY what we edited and updated in their report.

* * *New Report Numbers and Citation (new/important information below highlighted in yellow):

Series Name Number:
Natural Resource Report NPS/NRSS/NRR—2017/1425
Citation (on shown on page ii):
- we use sentence case here (only first letters, proper names, and acronyms capitalized).

A good rule-of-thumb for proper names that we use, is whether or not you can send a physical letter through the mail to that entity.

You cannot send a letter to: Sea Level Rise
But, you can send a letter to the Sea Level Rise Program, or Office, or Committee.

- if you update the series name/number with the one that I gave you above, your citation becomes:

TIC Number: 999/137852

*** Report Updates and Changes : here is what I updated and changed in your report.
How closely the rest of the report adheres to the "best practices" format and layout standards presented in our document templates, is up to the official Peer Review Manager for that report (Cat or John).

Front Cover and Title Pages (we are only this picky about the front and back cover pages):
- set your page margins to 0.75-inch on the left, top, and right; and 1-inch on the bottom (yours were 1-inch on all sides).
- updated the series name/number with the one that I gave you above.
- made sure that your cover image had alternate text (Section 508 - matches the caption on the following page).
- set the publication month and year to now.

Page ii:
- updated the sixth paragraph to the newer 2017 template standards (DOI/NPS prefers that we just add the hyperlink to the name of the webpage or website, and not spell-out the URL separately).
- updated the official report citation with the information that I gave you above.
- incorporated your new TIC number and the current month and
year into the last line on the page.

**Page Numbers:** Were showing up in different locations on different pages, so I deleted and re-added them to all pages.

This is a common MS Word bug that occurs whenever multiple versions of MS Word edit or create pages inside the same document (especially when more than two major versions were used).

**First Order Headings:** Set them all to begin at the top of a new page.

All first order headings must begin at the top of a new page.

The only exception to this rule is if you already have a first order heading at the top of a new page, then you may also place additional first order headings lower on the very same page.

**Lists of Contents, Figures, Tables, Photos, and Appendices:**
- checked for common software bugs. These were fine.
- updated the page numbers in the tables when I was finished with everything else.

**Figures - Made sure that figures:**
- stayed inside the page margins (Section 508 and document stability). They were fine.
- were in-line with text (no text wrapping—avoids export to PDF issues and prevents document crashes while editing).
- used consistent and predictable page placement in general (center-justified, same vertical distance from captions, etc.).

**Tables - Made sure that:**
- the table caption was located on the text line immediately above the table (and not in a table cell—avoids export to PDF issues).
- tables stayed inside the page margins (avoids export to PDF issues and prevents document crashes while editing). For tables that were larger than the page, I either:
  
  a) Shrank the size of the table to fit inside the page margins.
  b) Changed the page orientation to landscape orientation.
- since this was an NRSS report, reorganized tables to make them more Section 508 compliant.
  - replaced mid-table multiple column header rows with additional left-hand columns.
  - made sure that all captions and table notes were repeated above and below all sub-tables for tables that spanned multiple
- split and merged cells as needed such that all table cells would be read aloud correctly by screen readers for the visually and cognitively impaired (that software was designed to read tables aloud that are set up more like a spreadsheet).

- used a consistent and predictable layout scheme (left-justified, same border and background treatments, etc.).

**Inside Back and Outside Back Cover Pages:**
- made sure that the inside back cover occurred on an odd-numbered page.

This insures that the outside back cover is the absolute final printed page (no extra blank page).

- incorporated your new TIC number and the current month and year into the last line on the inside cover page.

**That's it!**

Hi Marcy -

My first destination on Monday was a hike in the snow below Lassen Peak. This is a beautifully scenic park.

We are currently in the meeting planning management of the numerous cultural landscapes here.

Patrick

Cc: Patrick Gonzalez <patrick_gonzalez@nps.gov>

Thanks so much Patrick. That helps a great deal.

I know FEMA hasn't incorporated climate change, but was not sure about other sources. Now that you mention it, I remember a discussion on a call a while back talking about David's research.

Hope work at Lassen is going well and you get out to see some of the park. Am headed to Shenandoah this weekend - can hardly wait.

Hi Marcy,

FEMA does not include projections of climate change in any of its flood risk maps, coastal or non-coastal. To my knowledge, USGS has not made publicly available a national flood and inundation data set for non-coastal areas that integrates projected climate change.

Dave Lawrence is looking into this, so you can ask him more.

Thanks,

Patrick

Hi Patrick,

Just got your out of office, noting that you're at Lassen.

Am sure you're busy there - if you have a chance to look at the follow up question below when you can, greatly appreciate it.

thanks again,

Marcy

Thanks so much for this Patrick. I just rewatched Maria's CCRP webinar presentation as well and have good notes down from that. Will work with her report for my presentation.

One more question to clarify - is there NPS consensus on how to look at or assess change in risk of inland/non-coastal flooding?

One of the presentations I'll be doing is in Milwaukee, which will have representatives from across the western states. Sea level rise and storm surge aren't their major concerns. So looking to confirm if we have a set of methods to do this yet, or if this is still more on our list of things to do.

Does that make sense?

Thanks again,
Marcy

quantitative results by individual park. The method is the same for all the parks.

NOAA has conducted spatial analyses of sea level rise for the entire U.S.:

NOAA Sea level rise viewer
https://coast.noaa.gov/slr

and coastal flood exposure for the east coast:

Coastal Flood Exposure Mapper
https://coast.noaa.gov/floodexposure/#/map

The NPS and NOAA results certainly go beyond the old FEMA flood maps. Maria's spatial outputs are broadly similar to the NOAA outputs, but Maria used the IPCC scenarios, while NOAA used non-standard U.S. scenarios.

I hope that your presentations go well for you!

Patrick

.................................................

Hi Patrick,
This is probably an enormous question - are there models or sources of data or approaches you would recommend for a state agency wanting to get a better understanding of future flood risks?

Perhaps in other words - sources of data or analysis beyond the FEMA flood risk maps?

Reason for asking - Cultural Resources Technical Preservation Services/State Tribal Local Planning and Grants programs are in the process of developing a new Preservation Brief that will provide guidance and standards for historic property owners who are planning or required to elevate those historic buildings. We're now preparing to do a series of three workshops in different parts of the country to listen to and work with State Historic Preservation Offices, as part of testing and collecting info that will go into the Brief.

I've been asked to give a climate change introduction for each workshop - with the general theme of how climate change is contributing to flood risk and sea level rise, and making the point that these risks are not going away, and that threats that pose these risks are likely to become more unpredictable.

I have some understanding of how NPS has been trying to track and model sea level rise (Maria Caffrey's work, Rob Young's team, for example). But as the nature of flooding risk can be highly specific to individual locations, I don't really have sense of what NPS is doing overall to capture it. So -- I guess that's my real question - do we have a method overall? Or have we been assessing it on a park-by-park basis?

I'd be grateful for thoughts or suggestions you might have. I need to send a set of slides off to the rest of the team by end of next week (26th), so if you're able to send on thoughts before then, that would be great.

Thank you so much,
Marcy

The NPS Sea Level and Storm Surge Projections Report report is available in the google drive folder and ready for the following Next Steps:

- Final check by co-authors Patrick Gonzalez and Cat Hawkins Hoffman.
- Final check by Science and Communication Team Members. (Babson, Cakir, Gallagher, Holly, Norton, Perez, Thieler (USGS))
- If you have edits or will not comment please notify Rebecca.
- Once complete, we will publish and post on IRMA with internal NPS access (initially & by 4/28 if we want to keep April 2017 text in report)

Plan for Release

- Website updates (Matt Holly)
- Rebecca Beavers and Larry Perez will coordinate release plans through Jeff Olson. Two paths forward are 1) internal release and 2) external release.
- Co-authors/Communication team members: please review/edit these documents that will be used to guide the release process. https://drive.google.com/open?id=0B2z-WBMLTvtHTFFpOVJjY3U0Snc

Status: the provided manuscript represents:

- Fagan's NRR series review that includes some reformatting of margins and some tables. (completed 4/21)
- Final edits to address comments from Ann Gallagher as presented on 4/19 communication team call. (completed 4/24)
- Content check by Maria Caffrey and Rebecca Beavers. (completed 4/25)

Thank you.

This is great...thanks for forwarding, Maria.

Just a quick update: Jeff Olson is now on a detail to GRCA for the next four months. Jeremy Barnum (also with WASO COMMS) will be filling in behind Jeff.

I forwarded Jeremy a copy of this report today, and provided him access to our media planning folder. We’ll work through Jeremy and Tom Crosson to get this released internally when we're ready to do so.

Matt,

Here is a copy of the final version of the report: https://drive.google.com/a/doi.gov/file/d/0BxhhWNH7lJJwYwc4TVBQUKYoRHe/view?usp=sharing

Fagan Johnson still needs to sign off on this and possibly reassign a new number to it, so don't post it to the website yet. I'm sharing this copy with you so you can see the layout and pull any figures you would like to use off of it. It's a rather large document that can take a couple minutes to download, so we should also make it so people have the option to download individual chapters to save time.

Thanks for your help on this!

Report Authors,

As you are aware, [redacted] As such, Maria, Rebecca and I are recommending we move forward on coordinating a soft, internal release through WASO Comms.

At the moment, we are planning to have Maria & Rebecca provide an internal webinar briefing (if necessary) to relevant personnel at 1:00 MT on Thursday, September 7. We then plan to release the report on Friday, September 15. On that date, the report will be made available on both IRMA and our Coastal Adaptation web page, likely with a supporting post to InsideNPS. We will not pursue a media release.

To support this release, we have compiled several materials in this share folder, to which all of you have edit access. In this folder you will find:

- a communications plan for the soft release
- a series of key messages
- a briefing statement
- a draft post to be published on InsideNPS
- a copy of the final report

Please take a moment to review these materials and make comments/edits as necessary by COB Tuesday, August 22. The following day, I will notify WASO Comms of our intended release to begin coordination.

Thanks,

L

Gents,

We are preparing for a soft, internal release of the Sea Level Rise and Storm Surge Projections report on September 15.

I just got the final version of the report from Rebecca, which you can find here on our share drive (document #5):

Z:\CCRP\Communication\105 - Media Requests\FY 17\03 - SLR Report

Unfortunately, its still in Word. According to Rebecca, "The version I am uploading went through a fair amount of 508 compliance/formatting. Please check and turn into a pdf if feasible."

Our intent is to make this report live on both IRMA and our Sea Level Change page on the release date. Fagan, will you be converting this final version to an accessible PDF before uploading to IRMA?

Thanks,

L

Hello Rebecca, everyone. Hopefully this will only require a few more minutes of your time.

The only reason that this email is long, is to provide additional guidance for what you still need to do (the three steps below), and details about exactly what I changed in your document (optional reading below the three steps).

Three Remaining Steps
(Download detailed instructions for all three steps)

Step 1. Download the updated MS Word file and final and updated MSF at:

https://drive.google.com/drive
/folders/0Bx0uAOormwkIMkYtLTU3M0pUdDQ?usp=sharing

**Maintaining your own copy of the final MSF is optional. We maintain multiple archived versions.

Step 2. Double-check and approve my updates and have Fagan export the final to PDF (Rebecca and Fagan).

a) Make your absolute final edits (if any), and send the VERY FINAL version of the .docx file back to Fagan.

If you want to know exactly what we updated in your report (optional), proceed to the ***Report Updates and Changes section below.

Make sure that there are no more changes when you send the report to Fagan. The sub-step below takes about 2-3 minutes per page. Changes after that point usually require starting over with the entire process (re-tagging all pages and not just the ones with changes).
b) **When all edits are final, Fagan will** export the final to PDF format and manually check fix the HTML-type tags on each page to meet current Section 508 of the Rehabilitation Act standards, such that the final document to be read aloud correctly by special screen readers for the visually and cognitively impaired.

**Step 3. Activate the draft IRMA record that I created for you, and upload the final PDF (Fagan).**

a) Go to this address to open the draft Data Store record that I created for you:

[https://irma.nps.gov/DataStore/Reference/Profile/2239974](https://irma.nps.gov/DataStore/Reference/Profile/2239974)

b) Click the *Actions* drop down menu near the top right of the screen and click *Edit* and update the Core and Subjects and Keywords information as you desire

**Note:** The Data Store search engine only searches on the bibliographic information you enter here. It does not search anything located inside any uploaded digital files.

c) When you are finished updating the Data Store bibliographic information, click the *Activate* button at the bottom-right of the page to save your changes and make the record visible to the public.

d) Go to the *Files and Links* tab. On the *Add* drop down menu, choose the *Digital File*. Use the file upload tools to upload the final PDF and *Activate* it (the PDF Holding also has to be *Active* to be downloadable).

(Download detailed instructions for all three steps)

***Everything below this point is just for people that really want to know EXACTLY what we edited and updated in their report.***

* * * *New Report Numbers and Citation (new/important information below highlighted in yellow):

**Series Name Number:**
Natural Resource Report NPS/NRSS/NRR—2017/1425
**Citation (on shown on page ii):**
- we use sentence case here (only first letters, proper names, and acronyms capitalized).

  A good rule-of-thumb for proper names that we use, is whether or not you can send a physical letter through the mail to that entity.

  **You cannot** send a letter to: **Sea Level Rise**

  But, **you can** send a letter to the **Sea Level Rise Program, or Office, or Committee**.

- if you update the series name/number with the one that I gave you above, your citation becomes:

TIC Number: **999/137852**

*** Report Updates and Changes : here is what I updated and changed in your report. ***

How closely the rest of the report adheres to the "best practices" format and layout standards presented in our document templates, is up to the official Peer Review Manager for that report (Cat or John).

**Front Cover and Title Pages (we are only this picky about the front and back cover pages):**
- set your page margins to 0.75-inch on the left, top, and right; and 1-inch on the bottom (yours were 1-inch on all sides).
- updated the series name/number with the one that I gave you above.
- made sure that your cover image had alternate text (Section 508 - matches the caption on the following page).
- set the publication month and year to now.

**Page ii:**
- updated the sixth paragraph to the newer 2017 template standards (DOI/NPS prefers that we just add the hyperlink to the name of the webpage or website, and not spell-out the URL separately).
- updated the official report citation with the information that I gave you above.
- incorporated your new TIC number and the current month and year into the last line on the page.
Page Numbers: Were showing up in different locations on different pages, so I deleted and re-added them to all pages.

This is a common MS Word bug that occurs whenever multiple versions of MS Word edit or create pages inside the same document (especially when more than two major versions were used).

First Order Headings: Set them all to begin at the top of a new page.

All first order headings must begin at the top of a new page.

The only exception to this rule is if you already have a first order heading at the top of a new page, then you may also place additional first order headings lower on the very same page.

Lists of Contents, Figures, Tables, Photos, and Appendices:
- checked for common software bugs. These were fine.
- updated the page numbers in the tables when I was finished with everything else.

Figures - Made sure that figures:
- stayed inside the page margins (Section 508 and document stability). They were fine.
- were in-line with text (no text wrapping—avoids export to PDF issues and prevents document crashes while editing).
- used consistent and predictable page placement in general (center-justified, same vertical distance from captions, etc.).

Tables - Made sure that:
- the table caption was located on the text line immediately above the table (and not in a table cell—avoids export to PDF issues).
- tables stayed inside the page margins (avoids export to PDF issues and prevents document crashes while editing). For tables that were larger than the page, I either:
  a) Shrank the size of the table to fit inside the page margins.
  b) Changed the page orientation to landscape orientation.
- since this was an NRSS report, reorganized tables to make them more Section 508 compliant:
  - replaced mid-table multiple column header rows with additional left-hand columns.
  - made sure that all captions and table notes were repeated above and below all sub-tables for tables that spanned multiple pages.
- split and merged cells as needed such that all table cells would be read aloud correctly by screen readers for the visually and cognitively impaired (that software was designed to read tables aloud that are set up more like a spreadsheet).

- used a consistent and predictable layout scheme (left-justified, same border and background treatments, etc.).

**Inside Back and Outside Back Cover Pages:**
- made sure that the inside back cover occurred on an odd-numbered page.

  This insures that the outside back cover is the absolute final printed page (no extra blank page).

- incorporated your new TIC number and the current month and year into the last line on the inside cover page.

**That's it!**

This is concerning your report that we approved for final publication on April 24, 2017.

We need someone to do the following over the next 3-5 work days:

1) Activate (make public) the Data Store record (https://irma.nps.gov/DataStore/Reference/Profile/2239974).

2) Upload the final PDF to the activated Data Store record.

   Please let me know if you cannot do this yourself, and we will export the last copy that we sent back to you to create an absolute final PDF on this end.

   Edits are locked once the final PDF has been made public.

Maria & Rebecca,

This far--to my recollection--I've only received the final version of the SLR report in Word format.

Has this report been exported as a 508 accessible PDF? This is really important, as this is the only accessible format we'll be able to post on our website.

I also recall vaguely that this report might already be hosted as an unpublished report on IRMA. If so, do you have a direct link?

-L
Team,

Just a quick reminder about this earlier request.

I’ll be forwarding these materials and our intent to release this report on September 15 to WASO Comms late tomorrow.

Best,

L

On Fri, Aug 18, 2017 at 2:00 PM, Perez, Larry <larry_perez@nps.gov> wrote:

Report Authors,

As you are aware, (b) (5) (b) (5) As such, Maria, Rebecca and I are recommending we move forward on coordinating a soft, internal release through WASO Comms.

At the moment, we are planning to have Maria & Rebecca provide an internal webinar briefing (if necessary) to relevant personnel at 1:00 MT on Thursday, September 7. We then plan to release the report on Friday, September 15. On that date, the report will be made available on both IRMA and our Coastal Adaptation web page, likely with a supporting post to InsideNPS. We will not pursue a media release.

To support this release, we have compiled several materials in this share folder, to which all of you have edit access. In this folder you will find:

• a communications plan for the soft release
• a series of key messages
• a briefing statement
• a draft post to be published on InsideNPS
• a copy of the final report

Please take a moment to review these materials and make comments/edits as necessary by COB Tuesday, August 22. The following day, I will notify WASO Comms of our intended release to begin coordination.

Thanks,

L

Jeremy,

As I mentioned briefly last week, NRSS has a forthcoming report entitled *Sea Level Rise and Storm Surge Projections for the National Park Service*. We are planning for a soft, internal release on Friday, September 15. On that date, the report will be made available on both IRMA and our public-facing *Sea Level Change* web page, likely with a supporting post to InsideNPS.

The primary audience for the report is park planners and managers. Additionally, it should be noted that this project did not generate any new data. Rather, the report is a synthesis of existing publicly available data sets. As such, we feel an internal release is most appropriate, and we will not pursue a media release.

To support this internal release, we have compiled several materials in this share folder, to which you and Jeff have edit access. Feel free to share access with additional members on your team as appropriate. In this folder you will find:

- a communications plan for the soft release
- a series of key messages
- a briefing statement
- a draft post to be published on InsideNPS
- a copy of the final report

Please review these materials at your earliest convenience. Please take note that--per the communication plan--we will rely on WASO Comms to provide notice to DOI, if necessary.

Finally, the report authors are ready to deliver a webinar briefing for relevant NPS personnel at 1:00 PM MT on Thursday, September 7, if necessary and/or requested. We are happy to coordinate this webinar through our office.

Thanks,

L

Fagan,

Per our convo today, here's the final version of the SLR & SS report. No further changes are anticipated, so we can move forward with final formatting and compliance.

As I mentioned we're shooting to have this posted to both IRMA and our Sea Level Change page on September 15. Please have a look when you can, and let's touch base early next week on what we think might be needed to turn this into a fully compliant PDF.

Thanks,

L.

Report Authors,

I had a call first thing this morning with WASO comms, and the SLR/SS report was a topic of discussion. There is some hesitation on their part to broach DOI with our intended report release, given what is playing out in Texas right now. That said, they are open to trying.

My inclination is to proceed with our intended release predicated on these four points:

- We fully intend a soft, internal release with no public communications
- The intended release date of September 15 is still well over two weeks away
- The aftermath of Harvey provides a topical note of relevance for the importance of this work
- We have good records to defend the intended release date against any charges that it is reactionary

Before I push forward, however, I want to get a pulse from each of you regarding your thoughts.

This looks great, and won't take much work on my end to do the final review.

Depending on my work-load doing other reports, my final review should be sent back to you within 3-5 work days of when you send me the final copy.

Take care.

Fagan,

Following up on our conversation:

- Sounds like you're good to go to get the report finalized and 508 compliant
- Let's plan to keep the report dated May 2017, as that was the date of report completion
- It does appear the report was already issued an NRR number: 2017/1425

Thank you so much for your help...please let me know if you need anything else.

I'll touch base with you again on this in a few days.

Larry,
This sounds fine to me. I don't think any of the projections significantly cross over into the area that is impacted by Harvey, so I really see this storm as outside the scope of anything this report will discuss.

Thanks for pushing this through. I really appreciate it.

Report Authors,

I had a call first thing this morning with WASO comms, and the SLR/SS report was a topic of discussion. There is some hesitation on their part to broach DOI with our intended report release, given what is playing out in Texas right now. That said, they are open to trying.

My inclination is to proceed with our intended release predicated on these four points:

- We fully intend a soft, internal release with no public communications
- The intended release date of September 15 is still well over two weeks away
- The aftermath of Harvey provides a topical note of relevance for the importance of this work
- We have good records to defend the intended release date against any charges that it is reactionary

Before I push forward, however, I want to get a pulse from each of you regarding your thoughts.

Jeremy,

Following our discussion yesterday morning, I consulted with the SLR/SS report authors. The consensus is that we would like to move forward on our intended September 15 release, predicated on these four points:

- We fully intend a soft, internal release with no public release
- The intended release date of September 15 is still well over two weeks away
- We feel the aftermath of Harvey provides a topical note of relevance for the importance of this work
- We have good records to defend the intended release date

Furthermore, Maria Caffrey--the lead author of the report--will end her term of service with the NPS in late October. Any delay in release could compromise our ability to have her provide briefings on the project and/or provide clarification on report results.

I will be providing notice up the line to NRSS that we will be moving forward on our intended release, and would appreciate your help in providing notice to DOI as appropriate.

I'll be in the office all day today if you'd like to touch base.

Thanks,

L

Guy, Brian & Ray,

As you are probably aware, several members of our team have collaborated on a completed report entitled *Sea Level Rise and Storm Surge Projections for the National Park Service*. We are coordinating with WASO Comms for a soft, internal release on Friday, September 15. On that date, the report will be made available on both IRMA and our public-facing Sea Level Change web page, likely with a supporting post to InsideNPS.

The primary audience for the report is park planners and managers. Additionally, the report is a synthesis of existing publicly available data sets. As such, we feel an internal release is most appropriate, and we will not pursue a media release.

To support this soft release, we have compiled several materials in this share folder, to which you all have access. Feel free to share this folder with additional relevant personnel as appropriate. In this folder you will find:

- a communications plan for the soft release
- a series of key messages
- a briefing statement
- a draft post to be published on InsideNPS
- a copy of the final report (not for distribution)

Please review these materials at your earliest convenience. Please take note that--per the communication plan--we are relying on WASO Comms to provide notice to DOI, as appropriate.

Finally, the report authors are ready to deliver a webinar briefing for relevant NPS personnel at 1:00 PM MT on Thursday, September 7, if necessary and/or requested. We can coordinate this webinar through our office.

Thanks,

L

Report Authors,

Just want to keep you in the loop on a couple of things:

- Following conversations between WASO Comms and NRSS leadership, we are electing to push back release of this report by a couple of weeks. The target date for release is now September 29.

- To accommodate this new timeline, we will also be rescheduling the webinar briefing (if requested/required) for Thursday, September 21 at 1:00 PM MT.

- Fagan Johnson is formatting the final report for 508 accessibility. We still expect this work to be complete by September 15.

At this time, Irma is churning as a major hurricane and Tropical Storm Jose has just formed in the Atlantic. We will, however, try to keep to this new release timeline, recognizing both the growing demand for the report data and the limited availability of the lead author.

Best,

L

FIND YOUR PARK
Fagan,

Not sure where you are in getting the compliance work done on this report, but a couple of things to be aware of:

- Following conversation with WASO Comms, we are electing to push back the date for the internal release to September 29. That gives us a bit more time.

- There may (or may not) be a need to change some text in the introduction. If so, the necessary changes should all be confined to one page of the report. More to come on that soon.

If you haven't yet completed the work, I'd recommend holding off until I forward clarification. If you have, it's hopefully not difficult to make changes to one page, tag accordingly, and bring into the existing document.

Thanks and have a great weekend,

L

Final Report: Providing Sea Level Change and Storm Surge Projections for Coastal Parks

Dr. Maria Caffrey, PI, University of Colorado Boulder
September 14, 2017

Maria Caffrey will be ending her role as project PI as the project closes effective September 29, 2017. Dr. Caffrey has worked with the project communication and science groups to deliver a final report that is expected to be internally released. The report has undergone peer review and is currently being edited for 508 compliance with an expected release date of September 29, 2017. Sea level and storm surge results have been uploaded to the Integrated Resource Management Applications (IRMA) portal and linked to a project page on the same portal (https://irma.nps.gov/DataStore/Reference/Profile/2240004).

Results from this project were presented at during a webinar hosted by the Climate Change Response Program on October 13, 2016 and at the George Melendez Wright Meeting in April 2017. Dr. Caffrey has offered her services to help brief staff and answer inquiries after the project terminates. She will also be working with NPS Denver Service Center GIS Program Lead Doug Wilder to make the sea level rise results from this project available in a web mapping format.
Looks good. Please send to Patrick and ask him to get it loaded in the PMIS statement.

Cat & Patrick,

I met with Rebecca and Maria this afternoon. Here's the final text of the Executive Summary and Introduction that we will include in the report.

Please call me ASAP if you have any questions or concerns: 970-267-2136.

Thanks,

L

______________________________

Executive Summary

Changing relative sea levels and the potential for increasing storm surges present challenges to national park managers. This report summarizes work done by the University of Colorado in partnership with the National Park Service (NPS) to provide sea level rise and storm surge projections to coastal area national parks using information from the United Nations Intergovernmental Panel on Climate Change (IPCC) and storm surge scenarios from National Oceanic and Atmospheric Administration (NOAA) models. This research is the first to analyze IPCC and NOAA projections of sea level and storm surge under climate change for U.S. national parks. Results illustrate potential future inundation and storm surge due to climate change under four greenhouse gas emissions scenarios. In addition to including multiple scenarios, the analysis considers multiple time horizons (2030, 2050 and 2100). This analysis provides sea level rise projections for 118 park units and storm surge projections for 79 of those parks.

Within the National Park Service, the National Capital Region is projected to experience the highest average rate of sea level change by 2100. The coastline adjacent to Wright Brothers National Memorial in the Southeast Region is projected to experience the highest sea level rise by 2100. The Southeast Region is projected to experience the highest storm surges based on historical data and NOAA storm surge models.

Sea level change and storm surge pose considerable risks to infrastructure, archeological sites, lighthouses, forts, and other historic structures located along the coast. Understanding projections for continued change can better guide protection of such resources for the benefit of long-term visitor enjoyment and safety. These results are intended to inform park planning and adaptation strategies for resources managed by the National Park Service.

______________________________

Introduction
Global sea level is rising. While sea levels have been gradually rising since the last glacial maximum approximately 21,000 years ago (Clark et al. 2009, Lambeck et al. 2014), anthropogenic climate change has significantly increased the rate of global sea level rise (Grinsted et al. 2010, Church and White 2011, Slangen et al. 2016, Fasullo et al. 2016). Earth continues to warm as human activities release carbon dioxide (CO₂) into the atmosphere (IPCC 2013, Mearns et al. 2013, Melillo et al. 2014). Continued warming of the atmosphere will cause sea levels to continue to rise, which will have a significant impact on how we protect and manage our public lands. The rate of warming depends on numerous factors considered by the Intergovernmental Panel on Climate Change (IPCC) under four different representative concentration pathways (RCPs; Moss et al. 2010, Meinshausen et al. 2011). Used as the basis for this report, the RCPs are climate change scenarios based on potential greenhouse gas concentration trajectories introduced in the fifth climate change assessment report of the Intergovernmental Panel on Climate Change (IPCC 2013). The IPCC’s process-based approach for estimating future sea levels contrasts with other estimates from semi-empirical techniques that commonly generate higher numbers.

This report provides estimates of sea level change due to climate change for 118 National Park Service units and estimates of storm surge for 79 of those units. As temperature increases, sea levels rise due to a number of factors that will be discussed in greater detail. As sea levels incrementally rise, periods of flooding caused by storms and hurricanes exacerbate the growing problem of coastal inundation (see list of terms). This can present considerable risks to infrastructure, archeological sites, lighthouses, forts, and other historic structures located within coastal park units. Understanding projections for continued change can better guide protection of such resources for the benefit of long-term visitor enjoyment and safety.

Peek et al. (2015) estimated that the cost of sea level rise in 40 National Park Service units could exceed $40 billion if these units were exposed to one-meter of sea level rise. The aim of this report is to: 1) quantify projections of sea level rise over the next century based on the latest IPCC (2013) models, and 2) show how storm surge generated by hurricanes and extratropical storms could also affect these parks.

When Hurricane Sandy struck New York City in 2012 it caused an estimated $19 billion in damage to public and private infrastructure (Tollefson 2013). This single storm cannot be attributed to anthropogenic climate change, but the storm surge occurred over a sea whose level had risen due to climate change. Extreme storms such as Hurricane Sandy have extreme costs. When Hurricane Sandy struck it was estimated to have a return period between a 398 year (Lin et al. 2016) and a 1570 year storm (Sweet et al. 2013). Currently, a 100 year storm surge in New York City could cost $2-5 billion and a 500 year storm surge could cost $5-11 billion (Aerts et al. 2013). Under future scenarios of increasing anthropogenic greenhouse gas emissions, models project increasing storm intensities (Mann and Emanuel 2006, Knutson et al. 2010, Lin et al. 2012, Ting et al. 2015). When this change in storm intensity (and therefore, storm surge) is combined with sea level rise, we expect to see increased coastal flooding and the permanent loss of land across much of the United States coastline. Increasing sea levels increase the likelihood of another Hurricane Sandy-sized storm surge striking New York City. Factoring in future sea level rise to these estimates reduces the potential return interval of a similar storm surge occurring by 2100 to between 50 years (Sweet et al. 2013) and 90 years (Lin et al. 2016).

Executive Summary

Changing relative sea levels and the potential for increasing storm surges present challenges to national park managers. This report summarizes work done by the University of Colorado in partnership with the National Park Service (NPS) to provide sea level rise and storm surge projections to coastal area national parks using information from the United Nations Intergovernmental Panel on Climate Change (IPCC) and storm surge scenarios from National Oceanic and Atmospheric Administration (NOAA) models. This research is the first to analyze IPCC and NOAA projections of sea level and storm surge under climate change for U.S. national parks. Results illustrate potential future inundation and storm surge due to climate change under four greenhouse gas emissions scenarios. In addition to including multiple scenarios, the analysis considers multiple time horizons (2030, 2050 and 2100). This analysis provides sea level rise projections for 118 park units and storm surge projections for 79 of those parks.

Within the National Park Service, the National Capital Region is projected to experience the highest average rate of sea level change by 2100. The coastline adjacent to Wright Brothers National Memorial in the Southeast Region is projected to experience the highest sea level rise by 2100. The Southeast Region is projected to experience the highest storm surges based on historical data and NOAA storm surge models.

Sea level change and storm surge pose considerable risks to infrastructure, archeological sites, lighthouses, forts, and other historic structures located along the coast. Understanding projections for continued change can better guide protection of such resources for the benefit of long-term visitor enjoyment and safety. These results are intended to inform park planning and adaptation strategies for resources managed by the National Park Service.

______________________________

Introduction

Global sea level is rising. While sea levels have been gradually rising since the last glacial maximum approximately 21,000 years ago (Clark et al. 2009, Lambeck et al. 2014), anthropogenic climate change has significantly increased the rate of global sea level rise (Grinsted et al. 2010, Church and White 2011, Slangen et al. 2016, Fasullo et al. 2016).
Earth continues to warm as human activities release carbon dioxide ($CO_2$) into the atmosphere (IPCC 2013, Mearns et al. 2013, Melillo et al. 2014). Continued warming of the atmosphere will cause sea levels to continue to rise, which will have a significant impact on how we protect and manage our public lands. The rate of warming depends on numerous factors considered by the Intergovernmental Panel on Climate Change (IPCC) under four different representative concentration pathways (RCPs; Moss et al. 2010, Meinshausen et al. 2011). Used as the basis for this report, the RCPs are climate change scenarios based on potential greenhouse gas concentration trajectories introduced in the fifth climate change assessment report of the Intergovernmental Panel on Climate Change (IPCC 2013). The IPCC’s process-based approach for estimating future sea levels contrasts with other estimates from semi-empirical techniques that commonly generate higher numbers.

This report provides estimates of sea level change due to climate change for 118 National Park Service units and estimates of storm surge for 79 of those units. As temperature increases, sea levels rise due to a number of factors that will be discussed in greater detail. As sea levels incrementally rise, periods of flooding caused by storms and hurricanes exacerbate the growing problem of coastal inundation (see list of terms). This can present considerable risks to infrastructure, archeological sites, lighthouses, forts, and other historic structures located within coastal park units. Understanding projections for continued change can better guide protection of such resources for the benefit of long-term visitor enjoyment and safety.

Peek et al. (2015) estimated that the cost of sea level rise in 40 National Park Service units could exceed $40 billion if these units were exposed to one-meter of sea level rise. The aim of this report is to: 1) quantify projections of sea level rise over the next century based on the latest IPCC (2013) models, and 2) show how storm surge generated by hurricanes and extratropical storms could also affect these parks.

When Hurricane Sandy struck New York City in 2012 it caused an estimated $19 billion in damage to public and private infrastructure (Tollefson 2013). This single storm cannot be attributed to anthropogenic climate change, but the storm surge occurred over a sea whose level had risen due to climate change. Extreme storms such as Hurricane Sandy have extreme costs. When Hurricane Sandy struck it was estimated to have a return period between a 398 year (Lin et al. 2016) and a 1570 year storm (Sweet et al. 2013). Currently, a 100 year storm surge in New York City could cost $2-5 billion and a 500 year storm surge could cost $5-11 billion (Aerts et al. 2013). Under future scenarios of increasing anthropogenic greenhouse gas emissions, models project increasing storm intensities (Mann and Emanuel 2006, Knutson et al. 2010, Lin et al. 2012, Ting et al. 2015). When this change in storm intensity (and therefore, storm surge) is combined with sea level rise, we expect to see increased coastal flooding and the permanent loss of land across much of the United States coastline. Increasing sea levels increase the likelihood of another Hurricane Sandy-sized storm surge striking New York City. Factoring in future sea level rise to these estimates reduces the potential return interval of a similar storm surge occurring by 2100 to between 50 years (Sweet et al. 2013) and 90 years (Lin et al. 2016).

Guy - Yesterday's NRSS Weekly Report included a reference (below) to the report in the Three Weeks Out section. I did not include it as one of the items I sent Justin Monetti for the report leadership shares with DOI.

(CCPR, GRD) Forthcoming Release of Sea Level Rise and Storm Surge Projections Report: A report entitled *Sea Level Rise and Storm Surge Projections for the National Park Service* will be made available through IRMA in the weeks ahead. The report provides estimates of sea level change for 118 coastal units of the National Park System. The date of anticipated release will be updated in subsequent submissions.

On Tue, Sep 19, 2017 at 8:29 AM, Perez, Larry <larry_perez@nps.gov> wrote:
Team,

A quick followup on this earlier notice: A final version of the Sea Level Rise & Storm Surge report is now available for your review in this shared folder (please do not distribute.)

It is our intent to make the report available through both IRMA and our public-facing Sea Level Change web page in late September, early October.

Please reach out to me by COB today if you have any concerns with proceeding. Otherwise, we will request WASO Comms provide notice to the Department at their discretion.

Best,

L

Guy, Brian & Ray,

As you are probably aware, several members of our team have collaborated on a completed report entitled *Sea Level Rise and Storm Surge Projections for the National Park Service*. We are coordinating with WASO Comms for a soft, internal release on Friday, September 15. On that date, the report will be
made available on both IRMA and our public-facing Sea Level Change web page, likely with a supporting post to InsideNPS.

The primary audience for the report is park planners and managers. Additionally, the report is a synthesis of existing publicly available data sets. As such, we feel an internal release is most appropriate, and we will not pursue a media release.

To support this soft release, we have compiled several materials in this share folder, to which you all have access. Feel free to share this folder with additional relevant personnel as appropriate. In this folder you will find:

- a communications plan for the soft release
- a series of key messages
- a briefing statement
- a draft post to be published on InsideNPS
- a copy of the final report (not for distribution)

Please review these materials at your earliest convenience. Please take note that--per the communication plan--we are relying on WASO Comms to provide notice to DOI as appropriate.

Finally, the report authors are ready to deliver a webinar briefing for relevant NPS personnel at 1:00 PM MT on Thursday, September 7, if necessary and/or requested. We can coordinate this webinar through our office.

Thanks,

L

Hi Patrick,

Sorry about that. I will follow up with the team regarding support for macs. We have been experiencing some issues with it not loading the first time for people, but it never occurred to me to check how it loads on a mac.

I was told it was on a public facing server, but that seems to not be the case so Steve (and maybe Rob) won't be able to review it. It will eventually be public facing once we have worked the bugs out.

Thanks for letting me know about these issues!

Hello everyone,

I am emailing because of your experience serving on the science team for the sea level and storm surge project. I have recently been working with some GIS experts at the National Park Service to create a sea level rise mapping website for NPS staff and members of the public to explore the data from my project without needing access to ArcGIS. Would it be possible for you to take a look at a beta version of the website and fill out a brief survey regarding your experience?

The beta version of the website can be accessed at: [link]

Please provide feedback using our survey: [link]

We would appreciate it if reviewers could provide feedback by COB Monday September 25th. I apologize for the short turn around time. I know some of you are dealing with the current storm season. Feel free to forward this to anyone you think might be an appropriate reviewer if you don't have the time to take a look.
Many thanks,

L

On Fri, Sep 8, 2017 at 11:59 AM, Johnson, Chalmers-Fagan <fagan_johnson@nps.gov> wrote:

Sounds good.

As long as the report was not released outside the NPS yet, you can edit anything between the first four pages (front cover to disclaimer page) and the last two pages (back cover pages).

Just make sure to update the dynamic lists of Contents, Figures, etc. just before you export the final to PDF format.

Oh, and for future reference

You should only ask for new report numbers when you know for sure that you will be uploading the final report PDF within 3-6 working days after we send the final reviewed document back to you.

The official publication date is tied directly to the day that I give it a new report number in a couple of off-site databases.

With our funding and staffing levels, we are not set up to manage giving out official report numbers and publication dates early.

And, we cannot change the date that was originally assigned later.

.

Thanks.

On Fri, Sep 8, 2017 at 10:46 AM, Perez, Larry <larry_perez@nps.gov> wrote: 

Fagan,

Not sure where you are in getting the compliance work done on this report, but a couple of things to be aware of:

- Following conversation with WASO Comms, we are electing to push back the date for the internal release to September 29. That gives us a bit more time.

- There may (or may not) be a need to change some text in the introduction. If so, the necessary changes should all be confined to one page of the report. More to come on that soon.

If you haven't yet completed the work, I'd recommend holding off until I forward clarification. If you have, its hopefully not difficult to make changes to one page, tag accordingly, and bring into the existing document.

Thanks and have a great weekend,

L

Fagan,

This looks good to me. Great job whipping those tables into compliance! :)

I added document metadata, set the bookmarks panel to open automatically, and saved a new version with "508 compliant" in the file name. I've uploaded this file to the same share folder, and we should plan to roll with that version.

Rebecca, Cat, and I are currently discussing how we would like to make this available on IRMA, so please do not upload until I touch base with you once more.

Many, many thanks for your persistent work on this,

L :)

On Tue, Sep 26, 2017 at 9:04 AM, Johnson, Chalmers-Fagan <fagan_johnson@nps.gov> wrote:

Take a look at the PDF here:

https://drive.google.com/drivefolders/0Bx0uAOormwkJmYtLU3M0pUdDQ

Those appendix tables would not export to PDF that cleanly, and it took me about six hours of manual tagging to make them Section 508 accessible.

Let me know if this works, and I'll activate the Data Store record and upload it (make it public).

Thanks.

Sounds good.

As long as the report was not released outside the NPS yet, you can edit anything between the first four pages (front cover to disclaimer page) and the last two pages (back cover pages).

Just make sure to update the dynamic lists of Contents, Figures, etc. just before you export the final to PDF format.

Oh, and for future reference
You should only ask for new report numbers when you know for sure that you will be uploading the final report PDF within 3-6 working days after we send the final reviewed document back to you.

The official publication date is tied directly to the day that I give it a new report number in a couple of off-site databases.

With our funding and staffing levels, we are not set up to manage giving out official report numbers and publication dates early.

And, we cannot change the date that was originally assigned later.

Thanks.

Fagan,

Not sure where you are in getting the compliance work done on this report, but a couple of things to be aware of:

- Following conversation with WASO Comms, we are electing to push back the date for the internal release to September 29. That gives us a bit more time.

- There may (or may not) be a need to change some text in the introduction. If so, the necessary changes should all be confined to one page of the report. More to come on that soon.
If you haven't yet completed the work, I'd recommend holding off until I forward clarification. If you have, it's hopefully not difficult to make changes to one page, tag accordingly, and bring into the existing document.

Thanks and have a great weekend,

L

Someone needs to upload the final version to the Data Store (official online archive for all NRR reports), and activate it (make it public).

https://irma.nps.gov/DataStore/Reference/Profile/2239974

We need to do this very, very, very soon.

The TIC office has a "published" date last April (the date that I first gave it a new report number...).

A vast majority of reports are uploaded and made public within 5 working days after we send back the final review...

"What's another word for Thesaurus?" Steven Wright

On Fri, Sep 8, 2017 at 10:46 AM, Perez, Larry
<larry_perez@nps.gov> wrote:

Fagan,

Not sure where you are in getting the compliance work done on this report, but a couple of things to be aware of:

- Following conversation with WASO Comms, we are electing to push back the date for the internal release to September 29. That gives us a bit more time.

- There may (or may not) be a need to change some text in the introduction. If so, the necessary changes should all be confined to one page of the report. More to come on that soon.

If you haven't yet completed the work, I'd recommend holding off until I forward clarification. If you have, its hopefully not difficult to make changes to one page, tag accordingly, and bring into the existing document.

Thanks and have a great weekend,
FUTURE PARK LEADERS of EMERGING CHANGE

NOW ACCEPTING PROJECT PROPOSALS FOR 2018!
NOW ACCEPTING PROJECT PROPOSALS FOR 2018!
I had a call with Ray yesterday...asked about status of getting a meeting together with Shawn Benge and Shawn Norton to get on the same page with SLR and messaging. He'll followup and get back to me.

Someone needs to upload the final version to the Data Store (official online archive for all NRR reports), and activate it (make it public).

https://irma.nps.gov/DataStore/Reference/Profile/2239974

We need to do this very, very, very soon.

The TIC office has a "published" date last April (the date that I first gave it a new report number...).

A vast majority of reports are uploaded and made public within 5 working days after we send back the final review...

Thanks.

<fagan_johnson@nps.gov> wrote:

Okay.

Please use the IRMA record that I created for you, and do not create a duplicate one.

https://irma.nps.gov/DataStore/Reference/Profile/2239974

Why?

The DOI Solicitor's Office mandates that the NRR, TIC, and IRMA ID values match in all of those systems, as well as in all of their individual off-site backup solutions (per records management policy).

We can't "get back" or change the previously archived records...

Fagan,

This looks good to me. Great job whipping those tables into compliance! :)

I added document metadata, set the bookmarks panel to open automatically, and saved a new version with "508 compliant" in the file name. I've uploaded this file to the same share folder, and we should plan to roll with that version.

Rebecca, Cat, and I are currently discussing how we would like to make this available on IRMA, so please do not upload until I touch base with you once more.
Many, many thanks for your persistent work on this,

L :)

On Tue, Sep 26, 2017 at 9:04 AM, Johnson, Chalmers-Fagan <fagan_johnson@nps.gov> wrote:

Take a look at the PDF here: https://drive.google.com/drive/folders/0Bx0uAOormwkIMkYtLTU3M0pUdDQ

Those appendix tables would not export to PDF that cleanly, and it took me about six hours of manual tagging to make them Section 508 accessible.

Let me know if this works, and I'll activate the Data Store record and upload it (make it public).

Thanks.

We are very close to having a final version...should be able to get it to you by COB Tuesday.

Thanks, and have a great weekend!

L

On Fri, Sep 8, 2017 at 11:59 AM, Johnson, Chalmers-Fagan <fagan_johnson@nps.gov> wrote:

Sounds good.

As long as the report was not released outside the NPS yet, you can edit anything between the first four pages (front cover to disclaimer page) and the last two pages (back cover pages).

Just make sure to update the dynamic lists of Contents, Figures, etc. just before you export the final to PDF format.

**Oh, and for future reference**

You should only ask for new report numbers when you know for sure that you will be uploading the final report PDF within 3-6 working days after we send the final reviewed document back to you.

The official publication date is tied directly to the day that I give it a new report number in a
couple of off-site databases.

  With our funding and staffing levels, we are not set up to manage giving out official report numbers and publication dates early.

  And, we cannot change the date that was originally assigned later.

.

Thanks.

Hi all -- Before I leave for the holidays, I wanted to provide a status update and "next steps" for [b] (5)

Sea Level Rise and Storm Surge Projections for the National Park Service; Natural Resource Report Series NPS/NRSS/NRR. Supported by CCRP, and conducted through agreement with the University of Colorado Boulder (Dr. Maria Caffrey). NPS lead is Rebecca Beavers.

This report has undergone peer review and will be part of the NRSS Natural Resource Report Series. A site is also being prepared in conjunction with the Park Atlas to enable parks to access the data developed through this project. Consistent with the approved NPS core messages regarding climate change, the report provides scientific modeling and analyses to help coastal park managers understand potential sea level rise levels specific to their parks. I've reviewed the document and support having it
completed in final design and disseminated through the NRR series, together with the associated data provided through the Park Atlas.

Next steps: Pending final design/layout (and preparation for the NRR series for the Caffrey et al report), both documents are ready for dissemination. Larry Perez is prepared to work with the NPS leads for both reports (Shawn Norton, Rebecca Beavers) in liaison with WASO Comms to determine the most efficient approach to provide information about, and access to the reports.

If you have concerns, questions, or suggestions, please let me know.

Maria Caffrey completion of BRD project; SLR_SS....pdf
BRD final GIP report/ SLR/Storm Surge Projections Report Status
Maria Caffrey turned in her final BRD project report today. Her major files have been transferred to the GRD shared drives (N & P); Rebecca & Hal have access to those files if needed.

The Sea Level/ Storm Surge Report has [b] (5) .

GRD Computer Maria has been using/ Save files for WRD Machine
GRD has requested the return of the computer that Maria Caffrey continued to use during her CCRP funded/BRD focused GIP position that concluded today. The GRD computer she was using is in her office, and the HelpDesk Ticket was submitted with a request to keep a copy of the computer profile, especially bookmarks, etc so those documents/links can be transferred to a WRD furnished machine when Maria is anticipated to start a new position with WRD in March 2018.

Please contact Kevin Noon or Alan Ellsworth for more details on that new position with WRD and associated computer.

PIV Card/ Active Directory Account
Maria Caffrey’s Task Agreement with the University of Colorado Boulder extends until March 31, 2018 so her PIV credential & Active Directory Account "should" remain valid through that date. WRD will work to extend the PIV credential for her new position during 2018.

Please contact Kevin Noon or Alan Ellsworth for more details on that new position with WRD and associated extension of the PIV card/Active Directory Account.

All,

Thanks very much for the productive call today. A quick followup:

**Current Status of Each Publication**

**SLR & Storm Surge Projections Report**
Fully peer reviewed, formatted, 508-compliant, & ready for release. Needs to be uploaded to IRMA. **Action Item:** Larry will work with NRSS IRMA leads to host the report online.

**Intended Release Strategy**

**SLR & Storm Surge Report**

**Target Release Date:** Thursday, February 15

- Report and data made available through IRMA with public access
- Report made available through the NPS Climate Change Subject Site
- Post announcement to Inside NPS
- Direct Distribution to 118 Coastal Parks
- Report author reports on findings as part of CCRP webinar series sometime later in the year (lead author currently out on maternity leave through March)

**Action Item:** Larry will update earlier release materials to reflect new plans & timelines.

**Action Item:** Jeff will discuss these plans with Jen Wyse and get back to us. Once comm plan and associated materials are updated, he will work through Jeremy Barnum to forward materials to the Department for review.

3. * Report Series - select series that is appropriate for the manuscript

☐ Natural Resource Data Series (NRDS) (proceed to sections 2 and 4 below)

Intended for the timely release of basic data sets and routine data summaries that are based on data collection and data management methods documented in established, peer-reviewed protocols. While QA procedures have been completed to assure the accuracy of raw data values, *analysis or interpretation of the data has not been completed and should not be included in NRDS manuscripts.* (see NRDS guidance and tips)

☒ Natural Resource Report (NRR) series (proceed to sections 3 and 4 below)

Intended for comprehensive information and analysis about natural resources and related topics concerning lands managed by NPS. NRR manuscripts may include quantitative data that are accompanied by analysis and/or interpretation; procedural documents such as protocols and standard operating procedures; planning or policy information; and/or resource management information.

Note: If the manuscript meets criteria for ‘Highly Influential Scientific or Scholarly Information’ as defined by the OMB Peer Review Bulletin (i.e., provides the sole or major component of information used in decision-making; or, by itself, leads to a change in the direction of decision-making or to a decision that creates a clear and substantial impact on important public policies or private sector decisions), publication should not occur in the NRR.

SECTION 2. NRDS Manuscript

This section applies only if you are publishing in the Natural Resource Data Series.

No peer review is required for these reports; however, program management review is recommended.

* Citation or link (preferred) to protocol associated with report:

n/a

SECTION 3. NRR Manuscript

This section applies only if you are publishing in the Natural Resource Report series. This series requires peer review.

This section should be completed by the program manager who is assuming responsibility for the content of the manuscript. Note: Authors can never hold the role of Program Manager or Peer Review Manager for a manuscript.

Current NPS peer review guidance requires that NPS scientific and scholarly activities comply with OMB Final Information Quality Bulletin for Peer Review (2004; 70 FR 2664-2677), and NPS Director’s Order (DO) #11B: Ensuring Quality of Information Disseminated by the National Park Service.

Peer review of the manuscript must comply with the NPS Interim Guidance on Peer Review. If the manuscript is submitted by or on behalf of the Inventory and Monitoring Division, it must also adhere to IMD-specific guidance.
3.1. Peer Review Manager

The peer review manager oversees the peer review process of this report, and assumes responsibility for the manuscript fully meeting NPS peer review guidance. Manuscripts submitted by the Inventory and Monitoring Division must also meet the latest version of the IMD Peer Review Policy (NPS-only).

The peer review manager recommends, to the program manager, the technical acceptance of the manuscript in a written record documenting the process. The peer review manager is also responsible for maintaining all records associated with the peer review process, including correspondence, comments, and responses.

* Peer Review Manager Name: John Gross

* Title: Climate Change Ecologist

3.2. Peer Review Summary

Briefly describe the major review comments addressed, and areas of the report that were revised during the peer review conducted by the Peer Review Manager.

Peer review was carried out using both internal and external reviewers. Reviewers were selected based on their expertise in one or more fields relating to coastal climate change, sea level change, or storm surge. The following people reviewed the document: Amanda Babson (NPS), Ann Gallagher (NPS), Larry Perez (NPS), Steve Nerem (University of Colorado), Bob Glahn (emeritus, NOAA), Doug Marcy (NOAA), Chris Zervas (NOAA), Rob Thieler (USGS), and Claudia Tebaldi (Climate Central). All peer review comments have been compiled in either spreadsheets as PDFs. Descriptions of how each comment was addressed are included in the spreadsheets. Comments covered the entire report. Peer reviewers were not supplied the GIS data referenced in this report. The GIS data will undergo a separate review.

Provide confirmation that peer and management review comments have been adequately incorporated into the final manuscript.

The report authors were responsible for the incorporation of peer and management comments into the final manuscript. These edits were reviewed by peer review manager John Gross to ensure that their edits adequately addressed the peer and management comments.

☐ Yes  ☒ No  Does the manuscript include any sensitive or commercially valuable information that may potentially jeopardize a park resource or that might justify a management review by a qualified individual? If yes, please explain

Click here to enter text.
☐ Yes  ☒ No

Is there policy-sensitive material in the manuscript that might justify a management review by an appropriate reviewer who can verify consistency with or clear and appropriate relation to NPS policy? A management review should be conducted if any material might not be consistent with NPS policy. If one of the reviewers is qualified to conduct such a review and has already done so, please explain.

Click here to enter text.
SECTION 4. Approval and Publication

4.1 Program Manager Approval
The NPS program manager has final authority to approve publication of the manuscript, and assumes responsibility for this report’s adherence to scientific integrity, administrative and policy standards.

* Program Manager Name: Cat Hawkins-Hoffman
* Title: Chief, Climate Change Response Program
* Date Approved for Publication: 4/14/2017

4.2. Report Numbers and Data Store Record Owners
Provide the name and email address of additional NPS employees who should receive the final publication review notice from the series manager, and who should review the associated NPS Data Store record.

Name: Rebecca Beavers
Email: Rebecca_Beavers@nps.gov

Name: Patrick Gonzalez
Email: Patrick_Gonzalez@nps.gov

The following information is completed by the publication series manager.

Report Series Number: Click here to enter text.
Technical Information Center (TIC) number: Click here to enter text.
NPS Data Store Reference Code: Click here to enter text.

Hi all -- Before I leave for the holidays, I wanted to provide a status update and "next steps" for

(b) (5)

Sea Level Rise and Storm Surge Projections for the National Park Service; Natural Resource Report Series NPS/NRSS/NRR. Supported by CCRP, and conducted through agreement with the University of Colorado Boulder (Dr. Maria Caffrey). NPS lead is Rebecca Beavers.
This report has undergone peer review and will be part of the NRSS Natural Resource Report Series. A site is also being prepared in conjunction with the Park Atlas to enable parks to access the data developed through this project. Consistent with the approved NPS core messages regarding climate change, the report provides scientific modeling and analyses to help coastal park managers understand potential sea level rise levels specific to their parks. I've reviewed the document and support having it completed in final design and disseminated through the NRR series, together with the associated data provided through the Park Atlas.

Next steps: Pending final design/layout (and preparation for the NRR series for the Caffrey et al report), both documents are ready for dissemination. Larry Perez is prepared to work with the NPS leads for both reports (Shawn Norton, Rebecca Beavers) in liaison with WASO Comms to determine the most efficient approach to provide information about, and access to the reports.

If you have concerns, questions, or suggestions, please let me know.

Cat,

Attached are recommended edits, as well as a version of the full report with relevant sections highlighted. Let's discuss quickly in advance of your sharing with Ray.

Rebecca, thanks very much for your input on this.

First Paragraph of Executive Summary
Changing relative sea levels and the potential for increasing storm surges present challenges to national park managers. This report summarizes work done by the University of Colorado in partnership with the National Park Service (NPS) to provide sea level rise and storm surge projections to coastal area national parks using information from the United Nations Intergovernmental Panel on Climate Change (IPCC) and storm surge scenarios from National Oceanic and Atmospheric Administration (NOAA) models. This research is the first to analyze IPCC and NOAA projections of sea level and storm surge under climate change for U.S. national parks. Results illustrate potential future inundation and storm surge due to climate change under four greenhouse gas emissions scenarios. In addition to including multiple scenarios, the analysis considers multiple time horizons (2030, 2050 and 2100). This analysis provides sea level rise projections for 118 park units and storm surge projections for 79 of those parks.

Third Paragraph of Executive Summary
Sea level change and storm surge pose considerable risks to infrastructure, archeological sites, lighthouses, forts, and other historic structures located along the coast. Understanding projections for continued change can better guide protection of such resources for the benefit of long-term visitor enjoyment and safety. These results are intended to inform park planning and adaptation strategies for resources managed by the National Park Service.

First Paragraph of Introduction
Global sea level is rising. While sea levels have been gradually rising since the last glacial maximum approximately 21,000 years ago (Clark et al. 2009, Lambeck et al. 2014), anthropogenic climate change has significantly increased the rate of global sea level rise (Grinsted et al. 2010, Church and White 2011, Slangen et al. 2016, Fasullo et al. 2016). Continued warming of the atmosphere will cause sea levels to continue to rise, which will have a significant impact on how we protect and manage our public lands. The rate of warming depends on numerous factors considered by the Intergovernmental Panel on Climate Change (IPCC) under four different representative concentration pathways (RCPs; Moss et al. 2010, Meinshausen et al. 2011). Used as the basis for this report, the RCPs are climate change scenarios based on potential greenhouse gas concentration trajectories introduced in the fifth climate change assessment report of the Intergovernmental Panel on Climate Change (IPCC 2013). The IPCC’s process-based approach for estimating future sea levels contrasts with other estimates from semi-empirical techniques that commonly generate higher numbers.

Second Paragraph of Introduction
Peek et al. (2018) estimate that the cost of sea level rise in 100 National Park Service units could exceed $23 billion if these units were exposed to one-meter of sea level rise. The aim of this report is to: 1) quantify projections of sea level rise over the next century based on the latest IPCC (2013) models, and 2) show how storm surge generated by hurricanes and extratropical storms could also affect these parks. [report to be cited as In Preparation]

Third Paragraph of Introduction
When Hurricane Sandy struck New York City in 2012 it caused an estimated $19 billion in damage to public and private infrastructure (Tollefson 2013). This single storm cannot be attributed to climate change, but the storm surge occurred over a sea whose level had risen due to climate change. Extreme storms such as Hurricane Sandy have extreme costs. When Hurricane Sandy struck it was estimated to have a return period between a 398 year (Lin et al. 2016) and a 1570 year storm (Sweet et al. 2013). Currently, a 100 year storm surge in New York City could cost $2-5 billion and a 500 year storm surge could cost $5-11 billion (Aerts et al. 2013). Under future scenarios of increasing greenhouse gas emissions, models project increasing storm intensities (Mann and Emanuel 2006, Knutson et al. 2010, Lin et al. 2012, Ting et al. 2015).

First Paragraph of Methods >> Sea Level Rise Data
Sea level rise is caused by numerous factors. Ice located on land and in the sea melts with the rise of mean global temperatures (IPCC 2013, Gillett et al. 2013, Frolicher et al. 2014). The melting of ice found on land, such as Greenland and Antarctica, is a significant driver of sea level rise.
First Paragraph of Discussion
Global mean sea levels have been rising since the last glacial maximum (Lambeck and Chappell 2001, Clark and Mix 2002, Lambeck et al. 2014). Church and White (2006) estimated that twentieth century global sea levels rose at a rate of approximately 1.7 mm/y, although this rate accelerated over the latter part of the century. Slangan et al. (2016) found that emissions of greenhouse gases have been the primary driver of global sea level change since 1970 and that the rate of sea level rise has increased over time (Table 1). Satellite altimetry data shows that present-day global relative sea levels are increasing at approximately 3.3 mm/y (Cazenave et al. 2014, Fasullo et al. 2016).

Caption of Figure 13
Radiative forcing for each of the Representative Concentration Pathways (RCPs). Positive radiative forcing means Earth receives more incoming energy from sunlight than it radiates to space. This net gain of energy will cause warming that can be measured as higher global average temperatures. RCPs replace the IPCC SRES scenarios. Note how RCP4.5 (yellow line) projections are slightly higher than RCP6.0 (gray line) in the early part of this century. Source: Meinshausen et al. 2011.

Sixth Paragraph of Discussion
These estimates do not include the latest data on changing land levels. The IPCC included estimates of global isostatic adjustment (Equation 1) in their predictions, but those do not include changes in land level due to other factors, such as earthquakes and groundwater extraction. We expect the latest, state-of-the-art land level estimates to be released by NASA in 2018.

U.S. Department of the Interior
National Park Service
Natural Resource Stewardship and Science
Fort Collins, Colorado
The National Park Service, Natural Resource Stewardship and Science office in Fort Collins, Colorado, publishes a range of reports that address natural resource topics. These reports are of interest and applicability to a broad audience in the National Park Service and others in natural resource management, including scientists, conservation and environmental constituencies, and the public.

The Natural Resource Report Series is used to disseminate comprehensive information and analysis about natural resources and related topics concerning lands managed by the National Park Service. The series supports the advancement of science, informed decision-making, and the achievement of the National Park Service mission. The series also provides a forum for presenting more lengthy results that may not be accepted by publications with page limitations.

All manuscripts in the series receive the appropriate level of peer review to ensure that the information is scientifically credible, technically accurate, appropriately written for the intended audience, and designed and published in a professional manner.

This report received formal peer review by subject-matter experts who were not directly involved in the collection, analysis, or reporting of the data, and whose background and expertise put them on par technically and scientifically with the authors of the information.

Views, statements, findings, conclusions, recommendations, and data in this report do not necessarily reflect views and policies of the National Park Service, U.S. Department of the Interior. Mention of trade names or commercial products does not constitute endorsement or recommendation for use by the U.S. Government.

This report is available in digital format from the Climate Change Response Program website and the Natural Resource Publications Management website. To receive this report in a format optimized for screen readers, please email irma@nps.gov.

Executive Summary

Changing relative sea levels and the potential for increasing storm surges due to anthropogenic climate change present challenges to national park managers. This report summarizes work done by the University of Colorado in partnership with the National Park Service (NPS) to provide sea level rise and storm surge projections to coastal area national parks using information from the United Nations Intergovernmental Panel on Climate Change (IPCC) and storm surge scenarios from National Oceanic and Atmospheric Administration (NOAA) models. This research is the first to analyze IPCC and NOAA projections of sea level and storm surge under climate change for U.S. national parks. Results illustrate potential future inundation and storm surge due to climate change under four greenhouse gas emissions scenarios. In addition to including multiple scenarios, the analysis considers multiple time horizons (2030, 2050 and 2100). This analysis provides sea level rise projections for 118 park units and storm surge projections for 79 of those parks.

Within the National Park Service, the National Capital Region is projected to experience the highest average rate of sea level change by 2100. The coastline adjacent to Wright Brothers National Memorial in the Southeast Region is projected to experience the highest sea level rise by 2100. The Southeast Region is projected to experience the highest storm surges based on historical data and NOAA storm surge models.

These results are intended to inform park planning and adaptation strategies for resources managed by the National Park Service.

Acknowledgments

This project was awarded funds through the NPS Servicewide Comprehensive Call (FY2013–2015) and augmented by funds from the Natural Resource Stewardship and Science Directorate’s Geologic Resources Division and Climate Change Response Program. We would like to thank the members of the communication advisory team (Rebecca Beavers, Lynda Bell, Maria Caffrey, Janet Cakir, Will Elder, Stanton Enomoto, Ann Gallagher, Matt Holly, Shawn Norton, Larry Perez, and Ryan Stubblebine) and science advisory team (Amanda Babson, Rebecca Beavers, Maria Caffrey, Patrick Gonzalez, Steve Nerem, and Rob Thieler) for their time and input into this project.

We would also like to thank Susan Teel and Caroline Rohe at Gulf Islands National Seashore for assistance in designing two wayside exhibits. Likewise, we thank Julie Whitbeck, Aleutia Scott, Kristy Wallisch, and Stacy Meyers for helping design, review, and install a wayside at Jean Lafitte National Historical Park and Preserve. Elizabeth Rogers and Kathy Krause helped design a wayside for Fire Island National Seashore. Doug Wilder, Dorothy Friday, and Neal Jander designed the online map viewer. We would also like to thank Jason Kenworthy, Rebecca Port, Michael Barthelmes, Bob Glahn, Doug Marcy, Chris Zervas, and Claudia Tebaldi for their assistance in editing and reviewing this document. Finally, we thank the National Oceanic and Atmospheric Administration and the Intergovernmental Panel on Climate Change for providing the respective storm surge and sea level rise data cited throughout this document.

List of Terms

The following list of terms are defined here as they will be used in this report.

*Bathtub model:* A simplification of the sea as bathtub of water to simulate a change in water level relative to the land. This model does not include other factors such changes in erosion or accretion that change alter the geometry of the coastline.

*Flooding:* The temporary occurrence of water on the land.

*Inundation:* The permanent impoundment of water on what had previously been dry land.

*Isostatic rebound:* A change in land level caused by a change in loadings on the Earth’s crust. The most common cause of isostatic rebound is the loading of continental ice during the Last Glacial Maximum in North America. The North American land surface is still returning to equilibrium after the melting of this continental ice in an effort to return to equilibrium with its original pre-loading state.

*National Park Service unit:* Property owned or managed by the National Park Service.

*Relative sea level:* Where the water level can be found compared to some reference point on land. This term is most frequently used in discussion of changes in relative sea level. A change in relative sea level could be caused by a change in water volume or a change in land level (or some combination of these two factors).
*Sea level:* The average level of the seawater surface.

*Sea level change:* This term is frequently used in reference to *relative* sea level change. This is the product of two main factors, 1) an increase in the volume of ocean water, and 2) a change in land level. These two factors can be broken down further into other drivers that will be discussed in greater detail in other sections. This term is sometimes mistakenly confused with the term *sea level rise.*

*Sea level rise:* An increase in sea level. This is the result of an increase in ocean water volume caused principally by melting continental ice and thermal expansion. This term is not to be confused with increasing *relative* sea level, which can also be caused by decreasing land levels.
Introduction

Global sea level is rising. While sea levels have been gradually rising since the last glacial maximum approximately 21,000 years ago (Clark et al. 2009, Lambeck et al. 2014), anthropogenic climate change has significantly increased the rate of global sea level rise (Grinsted et al. 2010, Church and White 2011, Slangen et al. 2016, Fasullo et al. 2016). Human activities continue to release carbon dioxide (CO₂) into the atmosphere, causing the Earth’s atmosphere to warm (IPCC 2013, Mearns et al. 2013, Melillo et al. 2014). Continued warming of the atmosphere will cause sea levels to continue to rise, which will have a significant impact on how we protect and manage our public lands. The rate of warming depends on numerous factors considered by the Intergovernmental Panel on Climate Change (IPCC) under four different representative concentration pathways (RCPs; Moss et al. 2010, Meinshausen et al. 2011). Used as the basis for this report, the RCPs are climate change scenarios based on potential greenhouse gas concentration trajectories introduced in the fifth climate change assessment report of the Intergovernmental Panel on Climate Change (IPCC 2013). The IPCC’s process-based approach for estimating future sea levels contrasts with other estimates from semi-empirical techniques that commonly generate higher numbers.

This report provides estimates of sea level change due to climate change for 118 National Park Service units and estimates of storm surge for 79 of those units. As temperature increases, sea levels rise due to a number of factors that will be discussed in greater detail. As sea levels incrementally rise, periods of flooding caused by storms and hurricanes exacerbate the growing problem of coastal inundation (see list of terms). Peek et al. (2015) estimated that the cost of sea level rise in 40 National Park Service units could exceed $40 billion if these units were exposed to one-meter of sea level rise. The aim of this report is to: 1) quantify projections of sea level rise over the next century based on the latest IPCC (2013) models, and 2) show how storm surge generated by hurricanes and extratropical storms could also affect these parks.

When Hurricane Sandy struck New York City in 2012 it caused an estimated $19 billion in damage to public and private infrastructure (Tollefson 2013). This single storm cannot be attributed to anthropogenic climate change, but the storm surge occurred over a sea whose level had risen due to climate change. Extreme storms such as Hurricane Sandy have extreme costs. When Hurricane Sandy struck it was estimated to have a return period between a 398 year (Lin et al. 2016) and a 1570 year storm (Sweet et al. 2013). Currently, a 100 year storm surge in New York City could cost $2–5 billion and a 500 year storm surge could cost $5–11 billion (Aerts et al. 2013). Under future scenarios of increasing anthropogenic greenhouse gas emissions, models project increasing storm intensities (Mann and Emanuel 2006, Knutson et al. 2010, Lin et al. 2012, Ting et al. 2015). When this change in storm intensity (and therefore, storm surge) is combined with sea level rise, we expect to see increased coastal flooding and the permanent loss of land across much of the United States coastline. Increasing sea levels increase the likelihood of another Hurricane Sandy-sized storm surge striking New York City. Factoring in future sea level rise to these estimates reduces the potential return interval of a similar storm surge occurring by 2100 to between 50 years (Sweet et al. 2013) and 90 years (Lin et al. 2016).
Format of This Report
This report contains five sections (introduction, methods, results, discussion, and conclusion), and presents results per park alphabetically by region. The 118 park units studied for this project cover six administrative regions: the Northeast, Southeast, National Capital, Intermountain, Pacific West, and Alaska. The scope of this project focuses on sea levels. The scope of this project did not include projected changes in lake levels, although interior waterways and lakes, especially the Great Lakes, are vulnerable to the effects of climate change. Further explanation on how to access the data from this project is available in the methods sections and accompanying appendices.

Frequently Used Terms
Definitions of the most basic terms used in this report occur on page ix. However, some terms require greater explanation for their use. For example, we follow the advice of Flick et al. (2012) in differentiating between the terms flooding and inundation. While many choose to use these terms interchangeably, we use the term “flooding” to describe the temporary impoundment of water on land. This usually results from storm activity and other short-lived events, such as periodic tidal action, and will therefore be used here in reference to the effects of a storm surge on land. “Inundation” is used to refer to the gradual permanent submergence of land that will occur due to sea level rise.

The terms sea level rise and sea level change are also used differently. Sea level rise refers only to rising water levels resulting from an increase in global ocean volumes. In most parts of the United States this increase in water volume will lead to increasing relative sea levels. However, in some parts of the country relative sea level is decreasing due to isostatic rebound. Figure 1 shows current sea level trends based on tide gauge records for United States that span at least 30-years of data.

For example, the Southeast Region of Alaska is experiencing a decrease in relative sea level. Alaska’s crust continues to rebound following the melting of large volumes of ice that occurred for centuries to millennia on land in the form of glaciers and ice fields. Alaska is tectonically complex with extensive faults that contribute to this crustal motion. Although the volume of ocean water in this region is increasing, the rate of sea level rise is less than the rate of isostatic rebound, resulting in a decrease in relative sea level. For this reason, we use the term “sea level change” as it includes regions that will experience a decrease in relative sea level (at least in the early part of this century) as well as those that will see increasing relative sea levels.
Figure 1. Sea level trends for the United States based on Zervas (2009), for all available data through 2015. Each dot represents the location of a long-term (>30 years) tide gauge station. Green dots represent stations that are experiencing the average global rate of sea level change. Stations depicted by yellow to red dots are experiencing greater than the global average (primarily driven by regional subsidence) and blue to purple dots are stations experiencing less than the global average (due to isostatic rebound or other tectonically-driven factors). Methods

This report summarizes work of a three-year project initiated in 2013, analyzing sea level change in 118 National Park Service units. Consultation with regional managers regarding units they considered to be potentially vulnerable to sea level change and/or storm surge resulted in selection of these 118 coastal park units (Appendix B). Project activities included the following:

1) Prepare sea level projections over multiple time horizons for each park unit.
2) Estimate potential exposure to storm surge using the National Oceanographic and Atmospheric Administration (NOAA) Sea, Lake, and Overland Surge from Hurricanes (SLOSH) Model and Tebaldi et al. (2012).
3) Create wayside exhibits\(^1\) with information about the impacts of climate change in the coastal zone for three National Park Service units.

Based on recommendations from regional personnel, three National Park Service units were selected as sites for wayside exhibits: Gulf Islands National Seashore, Jean Lafitte National Historical Park and Preserve, and Fire Island National Seashore. The finished wayside designs are in Appendix C. Each design is different, customized to reflect the messaging and/or themes of each unit.

Sea Level Rise Data

Sea level rise is caused by numerous factors. As human activities release CO\(_2\) and other greenhouse gases into the atmosphere, mean global temperatures increase (IPCC 2013, Gillett et al. 2013, Frolicher et al. 2014). Rising global temperatures cause ice located on land and in the sea to melt. The melting of ice found on land, such as Greenland and Antarctica, is a significant driver of sea level rise.

While the melting of sea ice is problematic from an oceanographic and heat budget perspective (primarily because it alters water temperatures and salinity and also because it changes the reflectance of solar energy from the surface), melting sea ice does not cause sea level rise. It is the melting of ice that is currently stored on land that raises global sea levels. Water level does not change when sea ice (ice wholly supported by water) melts. The volume of water in the sea remains the same whether it is frozen or liquid. The phase shift of water from solid to liquid does not displace an additional volume of water.

As ocean waters warm, the density of these waters also changes, causing thermal expansion. Thermal expansion was responsible for two-fifths of sea level rise from 1993 to 2010, while melting ice accounted for half (IPCC 2013). Table 1 lists the contribution to sea level rise from several key sources.

---

\(^1\) A wayside is an exhibit designed to be installed outside for visitors to learn about a particular subject (https://www.nps.gov/hfc/products/waysides/).

aData until 2009, not 2010.

bThis is not included in the total because these numbers have already been included in the Greenland ice sheet.

cThis is calculated as observed global mean sea level rise – modeled glaciers – observed land water storage. See table 13.1 in IPCC (2013) for more details.

The IPCC sea level rise projections used in this analysis follow a process-based model approach, which estimates sea level based on the underlying physical processes. This contrasts with semi-empirical models that combine past sea level observations with other variables or theoretical considerations, including, in some cases, expert opinion (surveys or interviews of professionals) (Rahmstorf 2010, Orlic and Pasaric 2013). Often the semi-empirical approach yields higher sea level estimates. IPCC (2013) uses coupled atmosphere-ocean general circulation models (AOGCMs) to simulate the processes of change rather than the statistical inferences of the semi-empirical approach. AOGCMs are considered a process-based technique, although some variables derive from semi-empirical methods (IPCC 2013).

Sea level rise estimates for 2050 and 2100 were taken directly from the IPCC (2013) regional climate models (RCMs) downscaled to a spatial grid resolution of 1˚ x 1˚ from AOGCMs. Because many park units require estimates for shorter time horizons that fit more closely with the expected lifetime of various projects, sea level rise projections for 2030 were calculated using IPCC RCM data for each sea level rise driver shown in Table 2, interpolated to 2030 for each RCP. All projections are reported relative to the period 1986–2005 (see Appendix B for further discussion). All geographic information systems (GIS) maps display the projected sea level on top of mean higher-high water (MHHW) using the most recent tidal datum epoch (1983–2001). MHHW is calculated by averaging the highest daily water level over a 19-year tidal datum epoch.

*aChanges in ice mass derived through direct observation and satellite data.

The standard error ($\sigma$) for each site estimate was not calculated because it was beyond the scope of this project. However, it can be calculated using the following equation and data available from the IPCC (2013, supplementary material):

$$\sigma_{tot}^2 = (\sigma_{steric/dyn} + \sigma_{smb\_a} + \sigma_{smb\_g})^2 + \sigma_{glac}^2 + \sigma_{IBE}^2 + \sigma_{GIA}^2 + \sigma_{LW}^2 + \sigma_{dyn\_a}^2 + \sigma_{dyn\_g}^2$$

Where: $steric/dyn = $ the global thermal expansion uncertainty plus dynamic sea surface height; $smb\_a =$ the Antarctic ice sheet surface mass balance uncertainty; $smb\_g =$ the Greenland ice sheet surface mass balance uncertainty; $glac = $ glacier uncertainty; $IBE = $ the inverse barometer effect uncertainty; $GIA = $ global isostatic adjustment; $LW = $ the land water uncertainty; $dyn\_a = $ Antarctica ice sheet rapid dynamics uncertainty; and, $dyn\_g = $ Greenland ice sheet rapid dynamics uncertainty.

Initial data were exported as GeoTIFF files for use in ArcGIS. For parks that crossed more than one pixel, an average sea level rise was calculated by weighting pixel values by the length of park shoreline in each pixel. A standard bathtub model approach was used to identify areas of projected inundation and flooding. In this method, projected sea level under climate change was determined by adding the IPCC RCM value to the current mean higher high water level. The land that would be at or below a projected sea level was then determined by analyzing digital elevation models (DEMs) of land elevation at spatial resolutions of 500 to 7000 m, depending on data availability for the areas of each park. DEM data for most regions were gathered from the NOAA digital coast website (https://coast.noaa.gov/digitalcoast). Areas of inundation and flooding are denoted in the maps (Appendix A) in blue. Additional low-lying areas that could be potentially inundated or flooded are shown in green (Figure 2). These low-lying areas do not appear to have any inlet or other pathway for water (based on our elevation datasets), although they should still be considered vulnerable to exposure to either groundwater seepage or potential flooding via breaching. The lack of high-resolution DEMs and time constraints prevented us from attempting a dynamic modeling approach (see limitations below). Maps were created to illustrate inundation for all park units for 2050 and
2100 under RCP4.5 and RCP8.5. These two represent a plausible range of scenarios between significant policy response (RCP4.5) and business as usual (RCP8.5).

Figure 2. An example of how areas of inundation appear in ArcGIS. In this example for the Toms Cove area of Assateague Island National Seashore, areas of inundation (RCP4.5 2050) appear in blue. Green shading indicates other low lying areas that are blocked from inundation by some impediment, but nonetheless could experience flooding should the physical barrier be removed or breached.

Storm Surge Data
NOAA SLOSH data estimate potential storm surge height at current (most recent tidal datum) sea level (NOAA 2016). The NOAA SLOSH model comprises the following three products (P-Surge, MEOW, and MOMs) that utilize three different modeling approaches (probabilistic, deterministic, and composite) to estimate storm surge.

P-Surge (also known as the tropical cyclone storm surge probabilities product) uses a probabilistic approach by examining past events to estimate the storm surge generated by a cyclone that is present and within 72-hours of landfall. It statistically evaluates National Hurricane Center data (calculated in part using a deterministic approach) including the official projected cyclone track and historical forecasting errors. It also incorporates astronomical tide calculations and variations in the radius of
maximum wind into this estimate. These rates of motion variables are then fit to a Cartesian or polar (depending on the location) grid (Jalesnianski et al. 1992).

The Maximum Envelope Of Water (MEOW) calculates flooding using past SLOSH output to create a composite estimate of the potential storm surge generated by a hypothetical storm. This product generates a worst-case scenario based on a hypothetical storm category that includes forward speed, trajectory of the storm when it strikes the coastline, and initial (mean vs. high) tide level that will also incorporate any historical uncertainty from previous landfall forecasts.

The final SLOSH product is the MOM (Maximum of MEOWs) model. MOM is a further composite approach that uses the forward speed, trajectory, and initial tide level data that is also used by MEOW to create a worst-of-the-worst scenario (or “perfect storm”). Storms are simulated for 32 regions (also known as operational basins, Figure 3) defined by NOAA. Data was imported into ArcGIS using the SLOSH display program. Maps were generated showing storm surge for all possible Saffir-Simpson hurricane categories for each site. While most sites had data for Saffir-Simpson hurricane categories 1−5 (Table 3), a few sites, such as Acadia National Park, were missing the highest category. NOAA did not model this scenario because it is considered extremely unlikely at a location that far north in the Atlantic Ocean.

![Figure 3. An example of the extent of an operational basin shown in NOAA’s SLOSH display program (http://www.nhc.noaa.gov/surge/slosh.php). The black area is the full extent of the operational basin for Chesapeake Bay.](image-url)

SLOSH MOM was used to estimate potential storm surge in 79 coastal park units. Unfortunately, MOM data do not exist for the remaining 39 units, so we supplemented this with data from Tebaldi et al. (2012) wherever possible. Tebaldi et al. (2012) used 55 long-term tide gauge records to calculate potential sea level and storm surge estimates above mean high water levels. We used the current 50-year and 100-yr return level data from their paper for any parks near a tide gauge. Unfortunately, due to insufficient coverage by tide gauges in this area, we were unable to use either Tebaldi et al. (2012) or SLOSH MOM data for the Alaska, Guam, and American Samoa park units. It is important to note that the Tebaldi (2012) and SLOSH MOM data differ in their methods of calculation making it inadvisable to compare storm surge values from the Pacific West Region to other regions. However, this method had to be used due to the lack of SLOSH MOM data for the Pacific West Region.

We recommend that parks planning for future hurricanes use information from one hurricane category higher than any previous storm experienced. Historical hurricane data from the International Best Track Archive for Climate Stewardship (IBTrACS; Knapp et al. 2010) is listed in Appendix D (Table D3) to allow staff to determine the highest Saffir-Simpson category hurricane to strike within 10 miles of each park unit. Applying information from one storm category higher than historical data may more closely approximate what could happen in the future, as storms are projected to be more intense under continued climate change (Emanuel 2005, Webster et al. 2005, Mendelsohn et al. 2012). However, we recommend caution in using this approach for any detailed (site-level) planning due to limitations discussed in the following section of this report.

Limitations

All projects of this nature have limitations that should be clearly described to ensure appropriate use and interpretation of these data.

Every effort has been made to incorporate any parks established after this project began (e.g. Harriet Tubman Underground Railroad National Monument); however, some maps might be missing due to lack of available boundary data in new units.

Sea level and storm surge estimates were derived using separate programs from the IPCC and NOAA, respectively. These numbers were then imported into GIS maps using the program ArcGIS. We used a bathtub modeling approach to map the extent of sea level rise and storm surge over every unit. Bathtub modeling simply simulates how high or how far inland water will go under different
climate change scenarios. It does not recognize changes in topography or other environmental or artificial systems that may exist or occur in response to encroaching water. Although the bathtub model is the most widely used technique for modeling inundation, it is also a simplistic approach to simulating how sea level rise will affect a landscape (Storlazzi et al. 2013). Dynamic models could simulate changes in flow around buildings or estimate how topographic features such as dune systems may migrate in response to inundation and flooding, but dynamic models also vary, which can be a severe limitation in trying to standardize data for summary analysis and comparison.

The maps provided through this analysis vary in horizontal and vertical accuracy depending on which digital elevation model (DEM) data were available at the time of mapping. This is discussed in more detail in the metadata that accompany each map. DEM data for most regions were gathered from the NOAA digital coast website (https://coast.noaa.gov/digitalcoast/) which uses source elevation data that either meet or exceed current Federal Emergency Management mapping specifications. These NOAA digital coast data were required to have a minimum root mean square error of 18.5 cm for low lying areas that were then corrected for MHHW using the NOAA VDatum model (Parker et al. 2003). USGS data were used for areas, such as Alaska, where digital coastal data were not available. We recommend referring to Schmid et al. (2014) for further discussion on potential uncertainty of this technique.

Although SLOSH MOM has the widest geographic storm surge coverage of any model in the US, storm surge data were not available for every part of the coastline. Every effort has been made by this project to bridge any gaps where SLOSH MOM does not exist. While the Tebaldi et al. (2012) data cover the California, Oregon, Washington, and southern Alaskan coastlines, they do not cover northern Alaskan, American Samoan, or Guam coastlines. These coastlines are vulnerable to storm surge but we could not find data that satisfied our standards of accuracy sufficiently to be included in our mapping efforts.

Furthermore, storm surge maps are only intended as a rough guide of how flooding caused by storm surge will look today. As more of the coastline becomes inundated we can expect coastal flooding patterns to also change accordingly. The SLOSH model is a multiple scenario approach that uses previous storms to estimate future storm surge. It cannot take into account changes in future basin morphology that could affect the fluid dynamics and propagation of coastal flooding.

SLOSH MOM is modeled using mean sea level (0 m NAVD88) and what NOAA terms “high tide” (which is not tied to the local tidal datum, but is actually a round number based on the modeled average high tide for the region). Jalesnianski et al. (1992) estimate surge estimates to be accurate +/-20%, although Glahn et al. (2009) discuss how others have found the P-Surge model to be more accurate than originally estimated. Such factors must be kept in mind when using these numbers for mapping.

### Land Level Change

It is important to include changes in land level while interpreting changes in sea level. The IPCC (2013) includes a limited amount of data regarding changes in relative sea level in their calculations of sea level change. Our sea level rise results include the IPCC estimates of how changes in land
level will change over time based on estimates of glacial isostatic adjustment. Land level change is an important variable when calculating relative sea level. Land levels have changed over time in response to numerous factors. Changes in various land-based loadings—such as ice sheets during the last glacial maximum—has been a significant cause of land level change in the U.S. Post-glacial isostatic rebound is the result of this pressure being released after the removal of ice sheets on the Earth’s crust. Land level can also be altered by other factors such as tectonic shifts, particularly along the Alaska and continental U.S. Pacific coastlines. These drivers can often prompt a relative increase or decrease in land level depending on location. Other factors such as aquifer drawdown and the draining of coastal swamps can create decreases in relative land level.

Quantifying how land levels are changing is difficult given the paucity of data available prior to modern satellite data. An upcoming NASA publication on land-based movement (Nerem pers. comm.) will help to address this data need, providing numbers for land-based movement across the country. Data from the NASA report can then be incorporated with sea level rise numbers from this analysis using the following equation (after Lentz et al. 2016):

\[
\text{Eq. 2} \quad ae = E_0 - e_i + R
\]

Where; \(ae\) is the adjusted elevation, \(E_0\) is the initial land elevation, \(e_i\) is the future sea level for either 2030, 2050, or 2100, and \(R\) is the current rate of land movement over time due to isostatic adjustments.

In the interim, tide gauges can provide further data regarding changes in land level, but should be used cautiously. We have listed tide gauge data for the rate of change in land level for tide gauges nearest to all units for this study in Appendix D; however, only Fort Pulaski National Monument and Golden Gate National Recreation Area have a long-term tide gauge on site. This lack of nearby long-term data can limit the accuracy of these numbers if they are applied to sea level change projections for almost all other parks units. We indicate in Table D1 which of the nearest tide gauges we do not recommend using to estimate land movement. This is because in many case the boundary of the park unit is located either too far away or on a different land mass to where the nearest tide gauge is, which increases the inaccuracy of this data. Land level changes were only reported for long-term tide gauges that had at least thirty years of data in order to ensure a statistically robust dataset. Based on these limited records, we estimate that seven park units are currently experiencing decreasing relative sea levels (Glacier Bay National Park, Glacier Bay Preserve, Katmai National Park, Kenai Fjords National Park, Lake Clark National Park, Sitka National Historical Park), although we cannot be certain of this number given that many of the park units are some distance from a tide gauge. We expect the release of the NASA data (Nerem pers. comm.) to help refine these estimates.

A discussion of the applicability of these land level numbers (with a natural resources manager or similar expert) should accompany use of individual park maps from this analysis to ensure that the nearest tide gauge to any particular project site is appropriate. Current rates of subsidence at these tide gauges range between +7.6 mm/y (Grand Isle, Louisiana) and -19 mm/y (Skagway, Alaska; Table D1). In selecting an appropriate tide gauge to use, variables including oceanographic setting, length of the record, completeness of data, and geography of the coastline must be considered. The
science team for this project decided against setting a threshold for how close a park unit should be to a long-term tide gauge based on considerations discussed above.

**Where to Access the Data**

All GIS data from this project are available at [https://irma.nps.gov/Portal](https://irma.nps.gov/Portal) for archiving by park.

A website discussing this project is available at the following address: [https://www.nps.gov/subjects/climatechange/sealevelchange.htm](https://www.nps.gov/subjects/climatechange/sealevelchange.htm)

The raw IPCC (2013) data can be downloaded using the following link: [http://www.ipcc.ch/report/ar5/wg1/docs/ar5_wg1_ch13sm_datafiles.zip](http://www.ipcc.ch/report/ar5/wg1/docs/ar5_wg1_ch13sm_datafiles.zip)
Results

Sea level and storm surge maps are in Appendix A. A full list of the 118 park units and a table listing sea level projections by park are available in Appendix D. Following the methods outlined above, we found that sea level rise projections across the 118 park units average between 0.45 m (RCP2.6) and 0.67 m (RCP8.5) by 2100. However, this number masks how these projections will vary geographically. Figure 4 shows these projections in more detail and provides sea level estimates by region. Error bars in Figure 4 denote the standard deviation for each average per region, further revealing how these numbers can vary. A high standard deviation and range signals that sea level estimates vary between units within regions, whereas a low standard deviation and small range are to be expected in smaller regions where sea level rise estimates do not cover such a large geographic area.

![Figure 4. Projected future sea level by NPS region for 2100 under RCP8.5 (the “business as usual” climate change scenario). Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each region.](image)

Based on the averages per region, we found that the shoreline within the National Capital Region is projected to experience the highest sea level rise by 2100 (0.80 m RCP8.5), although this number does not include the full extent of changes in land level over the same time interval. The shoreline near Wright Brothers National Memorial in the Southeast Region has the highest overall projected sea level rise (0.82 m, RCP8.5, 2100). Glacier Bay Preserve and Klondike Gold Rush National
Historical Park are tied for lowest projected sea level rise at 0.33 m using RCP8.5 for 2100. The Alaska Region also has the highest standard deviation among park units. The National Capital Region conversely has very little standard deviation due to the compact nature of the region (meaning that all of the parks units fell within the same raster cell). This is not to say that all of the parks will experience exactly the same rate of sea level rise, but that the IPCC model projected that sea levels could rise up to an average 0.80 m (RCP8.5) for that region by 2100. The sea level rise maps (discussed in the National Capital section below) illustrate differences among the National Capital parks in more detail.

Comparing RCP8.5 data for 2030 and 2050 (Figures 5 and 6, respectively) shows the Northeast Region almost tied with the National Capital Region in 2030 based on average projected sea level rise, with the National Capital Region ranked highest. The Alaska Region ranks lowest for all three time intervals followed by the Pacific Northwest region, Intermountain Region, and Southeast Region. The Northeast Region ranks second highest for 2050 and 2100.

**Figure 5.** Projected future sea level rise by NPS region for 2030 under RCP8.5 (the “business as usual” climate change scenario). Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each region.
Figure 6. Projected future sea level rise by NPS region for 2050 under RCP8.5 (the “business as usual” climate change scenario). Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each region.

Storm surge was mapped for 79 park units. We list data for one storm category higher than the highest historical storm in Table D3 in Appendix D. Some (31) park units did not have a historical storm path occurrence within 10 miles of their boundaries, so a Saffir-Simpson hurricane 1 was simulated for these locations. The lack of a historical storm does not mean that these parks are not subject to strong storms. It may merely be that these parks are in regions that either do not have extensive historical records or they experience strong storms, such as nor’easters, that behave differently and are not part of the NOAA database.

The Southeast Region has the strongest historical hurricanes (average of highest recorded storm categories = 2.79), followed by the Intermountain Region (average = 2.33), National Capital Region (average = 1.90), and the Northeast (average = 1.03). None of the historical data intersected with the 10-mile (16.1 km) buffers around the Alaska Region parks. The Pacific West Region has experienced some tropical depressions, particularly in Hawaii, but most of their storm surges are driven by other phenomena, such as mid-latitude cyclones or extreme tides (sometimes colloquially referred to as king tides). The strongest (highest winds) and most intense (lowest pressure at landfall) recorded historical storm to have impacted a park unit was the “Labor Day Hurricane” that passed within 10 miles of Everglades National Park in 1935. While this storm may have been the highest intensity storm, it is certainly not the most damaging or costly storm in National Park Service history.
Northeast Region
Colonial National Historical Park, Fort Monroe National Monument, and Petersburg National Battlefield have the highest projected sea level rise in 2050 and 2100, and, together with Edgar Allen Poe National Historic Site, Fort McHenry National Monument and Historic Shrine, Independence National Historical Park, and Thaddeus Kosciusko National Memorial (parks near coastlines) they also have the highest projected sea level rise for 2030. However, while these parks may have ranked highly, caution should be used in applying these results. Many of these parks do not have coastline and so these projections are based on sea level rise for the coastline adjacent to these parks. The maps in Appendix A show how the projected sea level rise may affect each of these parks. Colonial National Historical Park, Fort McHenry, and Fort Monroe National Monument are the only park units of this highest rise grouping that contain coastline with their boundaries.

Figure 7 shows the range of sea level projections for the Northeast Region for 2100, averaging between 0.49 m (RCP2.6) and 0.74 m (RCP8.5) of sea level rise by the end of the century. Acadia National Park had the lowest projected rates of sea level rise for 2030 (0.08–0.10 m), 2050 (0.14–0.19 m), and 2100 (0.28–0.54 m).

![Figure 7](image)

**Figure 7.** Projected future sea level rise by 2100 for the NPS Northeast Region under all of the representative concentration pathways. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each category.
Regarding storm surge, the highest recorded storm to have travelled within 10 miles of any of the 29 parks units identified for study was an officially unnamed hurricane in 1869 known colloquially as Saxby’s Gale, which was classified as a Saffir-Simpson 3 hurricane. The storm path passed present-day Boston National Historical Park and Roger Williams National Memorial. Figure 8 shows the estimated extent and height of a storm surge from category 3 hurricane striking Boston Harbor Islands National Recreation Area at mean tide.

**Figure 8.** Estimated storm surge created by Saffir-Simpson category 3 hurricane occurring at high tide near Boston Harbor Islands National Recreation Area. Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range).

**Southeast Region**

Historically, the Southeast Region has the highest intensity storms (highest Saffir-Simpson storm category); Everglades National Park has recorded a category 5 hurricane within 10 miles of its boundary, the colored areas in Figure 9 indicate the potential height and extent of a storm generated by two different categories of hurricane. A category 2 hurricane could completely flood the park.

Future storm surges will be exacerbated by future sea level rise nationwide; this could be especially dangerous for the Southeast Region where they already experience hurricane-strength storms.
Moreover, sea level rise projections only include changes in land movement due to glacial isostatic adjustment and do not include the full range of drivers of potential changes in land level. Using Table D1 from Appendix D as a rough guide, changing land level for parks near tide gauges can be evaluated. For example, the Eugene Island, Louisiana tide gauge’s current rate of sea level rise is the highest in the country at 9.65 mm/y, owing in part to the large rate of subsidence in the region (Figure 1). Using the nearest tide gauge to Jean Lafitte National Historical Park and Preserve (Grand Isle, Louisiana, gauge 8761724) we can estimate that land will subside by 7.60 mm/y. Applying this estimate of subsidence (using a baseline of 1992) to our RCP8.5 projections, the park could experience approximately 0.41 m of relative sea level rise by 2030 followed by 0.69 m by 2050 and 1.50 m by 2100. This is an inexact estimate of the land movement for the park given that Jean Lafitte National Historical Park and Preserve is approximately 60 miles (97 km) from the tide gauge; still, factoring in changes in land level, we can see that relative change in sea level is more than double the projected change in sea level using the IPCC estimates alone.

This analysis projects that, by 2100, the shoreline adjacent to Wright Brothers National Memorial may have the greatest sea level rise among the Southeast Region’s parks (0.82 m RCP8.5). Given elevations within the park, this may not inundate a large area of the memorial, unless combined with other factors such as a storm surge. For example, the park may be almost completely flooded if a category 2 or higher hurricane strikes on top of inundation from sea level rise.

Nearby Cape Hatteras and Cape Lookout National Seashores are projected to experience sea level rise of up to 0.79 m and 0.76 m, respectively (RCP8.5) by 2100, resulting in large areas of inundation. While sea level rise around these national seashores may not be as high as what has been projected for Wright Brothers National Memorial, they serve as examples of how caution must be used when using these numbers to assess which park units are most vulnerable to sea level rise. Other factors, such as percent of exposed land, changes in land movement, and adaptive capacity must also be taken into account for vulnerability analyses (Peek et al. 2015).
Figure 9. SLOSH MOM storm surge maps for a Saffir-Simpson category 1 (left) versus category 2 hurricane striking Everglades National Park at mean tide (right). Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range).
National Capital
National Capital Region has minimal variability in projected sea level rise because all park units selected for study are adjacent to the same section of coastline that was modeled. Their proximity also explains why they share the same storm history. Despite these similarities, projected sea level rise may affect each individual park unit differently based on local topography. The strongest storm recorded within 10 miles (16.1 km) of the National Capital Region parks was a Saffir-Simpson category 2 hurricane that struck the city in 1878. While the 1878 storm caused relatively little damage, we can expect a significantly larger amount of damage if a similar storm struck the city again given considerable development now existing in the area. Figure 10 shows the extent of flooding caused by a Saffir-Simpson category 2 hurricane. A storm surge measuring more than 3 m could travel up the Potomac River causing large amounts of flooding. Such a storm surge could be worse by the end of this century given projected sea level rise around the Capital Region of up to 0.8 m.

Figure 10. A SLOSH MOM map showing storm surge height and extent created by a Saffir-Simpson category 2 hurricane striking the Washington D.C. region at high tide. Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range).
IPCC/SLOSH models showed either storm surge or sea level rise (or some combination of the two) affecting every National Capital Region park included in this analysis, with the exception of Harpers Ferry National Historical Park. Our mapping efforts revealed that Harpers Ferry National Historical Park (located approximately 149 m above sea level) is unlikely to experience any impacts of sea level rise due to its elevation and is unlikely to be damaged by storm surge from a hurricane, given its relatively protected location behind several dams along the Potomac and Shenandoah Rivers.

Sea level rise alone is not expected to spread very far into Washington D.C., although a large section on the east side of Theodore Roosevelt Island could be inundated. However, storm surge flooding on top of this sea level rise would have widespread impacts.

**Intermountain Region**

The Intermountain Region covers mostly inland park units stretching from Texas to Montana. Within the region, only three park units in Texas are subject to sea level change: Big Thicket National Preserve, Palo Alto Battlefield National Historical Park, and Padre Island National Seashore. Of these, Padre Island National Seashore may experience the greatest effects of sea level and storm surge; sea level is projected to rise 0.46–0.69 m (RCP2.6–8.5, Figure 11) by 2100. The same amount of sea level rise is projected for the shoreline near Palo Alto Battlefield National Historical Park, but inundation is not projected to extend far enough to reach the park. Palo Alto Battlefield National Historical Park has no history of being within 10 miles of any hurricane, making the site unlikely to be flooded by storm surge. SLOSH MOM models for the park unit show that that the region would have to have either a Saffir-Simpson category 4 hurricane striking at high tide or a category 5 hurricane striking at any tide in order for the park to experience any storm surge. On the other hand, Figure 12 shows that Padre Island National Seashore, located to the east of Palo Alto Battlefield National Historical Park, historically was within 10 miles of a category 4 hurricane. SLOSH MOM data show that should a category 4 hurricane occur here again, it would likely flood almost the entire island.

Storm surge could potentially travel up the Neches River and flood the southernmost part of Big Thicket National Preserve, although both artificial and natural storm surge defenses in Beaumont, Texas, to the south of the preserve, may buffer it from any surge.
Figure 11. Projected future sea level rise by 2100 for the NPS Intermountain Region under all of the representative concentration pathways. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation from each mean. Blue bars mark the full range of sea level estimates for each category.
Figure 12. A SLOSH MOM map showing storm surge height and extent created by a Saffir-Simpson category 4 hurricane striking the southwestern Texas region at mean tide. The dark green line around the island represents the boundary of Padre Island National Seashore. Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range).
Pacific West Region
The Pacific West Region identified 24 park units for analysis in this study that could be vulnerable to sea level rise and/or storm surge. These units occur over a large area that includes California, Oregon, Washington, Hawaii, American Samoa, and Guam. War in the Pacific National Historical Park in Guam has the highest projected sea level rise at 0.68 m (RCP8.5) by 2100, and shares the highest projected sea level rise with almost all of the Hawaiian park units in 2030 and 2050. The average projected sea level rise range is 0.40–0.58 m (RCP2.6–8.5) by 2100 for the whole region; high standard deviations (0.04 m and 0.08 m for RCP2.6 and RCP8.5, respectively) indicate that park-specific projections vary widely across the region.

At the other end of the spectrum, projected sea level rise around Washington’s Olympic Peninsula and in the San Juan Islands, affecting Ebey’s Landing National Historical Reserve, Olympic National Park, and San Juan Island Historical Park, is expected to occur more slowly, reaching a maximum 0.46 m (RCP8.5) by 2100. This region is subject to tectonic shifts and continuing land movement due to isostatic rebound, further complicating sea level projections. Long-term tide gauge records at Neah Bay, Washington (gauge 9443090), and Tofino, British Columbia, Canada (gauge 822-116), show relative sea levels currently decreasing while tide gauges in Port Angeles, Washington (gauge 9444090), Victoria, Canada (gauge 822-101), and Seattle, Washington (gauge 9447130), show it to be increasing (Zervas 2009). Our projections indicate rising sea level in this region throughout this century, although further investigation of localized changes in land movement could shed more light on this matter.

Park units in the Pacific West Region need to be concerned about potential future storms that could travel along the eastern Pacific Ocean’s increasingly warmer waters. Because of the relative lack of hurricanes in this region historically, we used data from Tebaldi et al. (2012), which includes anomalous surges that could be created by storms, and other factors (very high tides sometimes referred to as king tides). Based on the Tebaldi et al. (2012) data, La Jolla, California (gauge 9410230), has the lowest 100-year storm surge (0.95 m) and Toke Point, Washington (gauge 9440910), has the highest 100-year storm surge (1.96 m) in the Pacific West Region. Tebaldi et al. (2012) did not analyze storm data for Hawaii, Guam, or American Samoa, although IBTrACS (Knapp et al. 2010) does have hurricane records for these areas. Only tropical depressions have been recorded within 10 miles of almost all of the Hawaiian park units we analyzed (Haleakala National Park, Hawaii Volcanoes National Park, Kalaupapa National Historical Park, Kaloko-Honokohau National Historical Park, Puukohola Heiau National Historic Site, and World War II Valor in the Pacific National Monument).

Alaska Region
The Alaska Region has the lowest average projected sea level rise (0.28–0.43 m by 2100) compared to the five regions described above. Glacier Bay National Park and Preserve and Klondike Gold Rush National Historical Park in southeastern Alaska share the lowest projected sea level rise (0.33 m, RCP8.5, 2100) while Bering Land Bridge National Preserve on the west coast of the state has the highest projected sea level rise (0.60 m, RCP8.5, 2100).
Figure 1 shows how current relative sea levels vary across the state. Land levels are rapidly rising in the southeast of the region due to isostatic rebound and other tectonic shifts. The net result of these increasing land levels is decreasing relative sea levels for at least the early part of this century. Relative sea level in Skagway, Alaska is decreasing at an average rate of 17.6 mm/y (Zervas 2009). Despite melting ice and other factors outlined in Table 1 that increase ocean water volume, the amount of rising water is insufficient to keep up with land level changes. Seven park units (Glacier Bay National Park, Glacier Bay National Preserve, Katmai National Park, Kenai Fjords National Park, Lake Clark National Park, Sitka National Historical Park) are identified as potentially having decreasing relative sea levels based on the nearest tide gauge data to each of these parks. None of these parks have long-term tide gauges with data spanning at least thirty years. A great strength of using the IPCC (2013) process-based model approach is that, unlike many other semi-empirical models, it does not rely on long-term tide gauge records to statistically project future sea levels. However, sea level projections in this analysis do not include changes in land level. The estimates that we report here represent the expected rise due to water volume expansion alone near to each of these park units. Table D1 shows how land levels are changing at long-term tide gauges across the country. However, given that all of these park units are located far from a tide gauge and that the region is relatively geologically complex, we do not recommend using the land movement numbers from the nearest tide gauge for any of the Alaskan parks.

Storm surge is also very difficult to model for this region. Historically, many of the parks had sea ice along the coastline that helped protect these parks from storm surge. Consequently, NOAA does not have SLOSH MOM models for this region. IBTrACS data (Knapp et al. 2010) show a few storm paths that have moved towards the region, but these types of storms typically do not make landfall once they move over colder waters. Alaska does hold the record for the highest intensity (lowest central pressure) storm (Duff 2015). A downgraded super typhoon, Nuri, struck Adak Island, Alaska, in 2014 with recorded winds gusting up to 122 mph. It is impossible to determine an average or peak historical storm surge without adequate tide gauge data.
Discussion

Global mean sea levels have been rising since the last glacial maximum (Lambeck and Chappell 2001, Clark and Mix 2002, Lambeck et al. 2014). Church and White (2006) estimated that twentieth century global sea levels rose at a rate of approximately 1.7 mm/y, although this rate accelerated over the latter part of the century. Slangan et al. (2016) found that emissions of greenhouse gases from human activities have been the primary driver of global sea level change since 1970 and that the rate of sea level rise has increased over time (Table 1). Satellite altimetry data shows that present-day global relative sea levels are increasing at approximately 3.3 mm/y (Cazenave et al. 2014, Fasullo et al. 2016).

The IPCC (2013) projects that, without greenhouse gas emissions reductions, this rate will increase, and that global average sea levels could rise by 0.40–0.63 m (RCP2.6–8.5) by 2100. We used regional sea level projections from the IPCC (2013) generated for 2050 and 2100 in combination with our interpolated projections for 2030 to estimate the amount of sea level rise 118 coastal national park units could experience in the future. Our projections are based on the new representative concentration pathways (Moss et al. 2010, Figure 13), using a process-based model approach.

![Figure 13](image)

**Figure 13.** Radiative forcing for each of the Representative Concentration Pathways (RCPs). An increase in radiative forcing (due to the loading of anthropogenic gases into the atmosphere) will result in higher global average temperatures. RCPs replace the IPCC SRES scenarios. Note how RCP4.5 (yellow line) projections are slightly higher than RCP6.0 (gray line) in the early part of this century. Source: Meinshausen et al. 2011.
Numerous academic articles use mostly semi-empirical models (Rahmstorf 2007) to estimate sea level rise regions across the U.S. The IPCC (2013) lists several semi-empirical sea level rise estimates, all of which result in projections of future sea level that are higher than the IPCC (2013) approach. The differences in these approaches can be attributed to many factors. For example, some of the older papers may have higher sea level estimates because they are based on the older IPCC SRES scenarios (e.g. Vermeer and Rahmstorf 2009, Grinsted et al. 2010, Jevrejeva et al. 2010). Other papers may include input from “expert elicitations” in their sea level projections, in which experts provide their opinion on how much sea level (or a related factor) could rise in the future (e.g. Bamber and Aspinall 2013, Jevrejeva et al. 2014, Horton et al. 2014). Some published articles criticize the IPCC sea level estimates as being too conservative or underestimating rates of future sea level change (e.g. Kerr 2013, Horton et al. 2014). Church et al. (2013) addresses these criticisms by explaining how the IPCC define the probability and likelihood of their estimates, and so they are not discussed in detail here. Recent analyses by Clark et al. (2015) further support the findings of the IPCC.

A key strength of the methods used in this analysis lies in providing a unified approach to identify how sea level change may affect all coastal park units across the National Park System, rather than relying on sea level data generated for specific areas. Our analyses revealed that the National Capital Region is projected to experience the greatest increase in sea level (not taking into account changes in land level). This rise will affect each of the region’s units in different ways depending on the elevation of the individual unit, but it could be significant if combined with a storm surge from a storm such as the Saffir-Simpson category 2 hurricane in 1878.

At the individual park level, IPCC projections reveal the sea level along the coastline adjacent to Wright Brothers National Memorial could rise up 0.82 m (RCP8.5) by 2100, which could lead to significant flooding if the dynamic landforms are not able to keep pace with such high rates of sea level rise. In addition, storm surge impacts at this higher sea level would be significant. The Southeast Region as a whole is generally susceptible to inundation and flooding due to its low-lying nature in many places, particularly in Cape Hatteras and Cape Lookout National Seashores. Our sea level rise maps (Appendix A) highlight how much all of these park units may be affected.

These estimates do not include the latest data on changing land levels. The IPCC included estimates of global isostatic adjustment (Equation 1) in their predictions, but those do not include changes in land level due to other factors, such as earthquakes and groundwater extraction. We expect the latest, state-of-the-art land level estimates to be released by NASA in 2017. In the meantime, we can roughly estimate relative sea level change for a small number of parks based on current rates of subsidence gathered from nearby long-term tide gauge data. We project Jean Lafitte National Historical Park and Preserve to have the greatest relative sea level increase based on the current rate of land movement. Our sea level projections agree with current sea level trends in showing that the southeast Alaska region is experiencing the least amount of sea level rise of anywhere in the National Park System.
Sallenger et al. (2012) discussed how changes in Atlantic Ocean temperatures and salinity (resulting from changes in circulation) could lead to changes in sea level that could create a 1000-km long “hotspot” along the North Atlantic coast from Cape Cod, Massachusetts to Cape Hatteras, North Carolina. We estimate that almost all of the coastal park units in this area would be flooded under these conditions.

It is unknown exactly to what degree future storm surge will affect the Alaskan park units. Accurate long-term (>30 years) storm surge data do not exist for the Alaska region. Even if such data did exist, it would be not be analogous to future conditions in the region because sea ice that had previously protected the shores for many of the western Alaska park units melts to reveal an easily erodible coastline (Frey et al. 2015). The warming of ocean waters in the Gulf of Alaska and Pacific Ocean could also make it more conducive for more storms like Typhoon Nuri to travel north without losing energy as under historic conditions.

The Pacific West Region shows high variability among parks. War in The Pacific National Historical Park in Guam ranks highest in projected sea level rise among units in the Pacific West Region. The large area of the region partly explains the relatively high standard deviation in results for the region. The tectonically complex setting of many of the region’s parks also complicates future sea level estimates. Changes in land movement are somewhat gradual nationwide in comparison to Alaska and the Pacific West Region, especially where earthquakes can rapidly change the position of the land relative to the sea.

Island park units in general are particularly exposed to the impacts of sea level change and storm surge. Many of the barrier island parks, such as Fire Island National Seashore, Assateague Island National Seashore, Palo Alto Battlefield National Historical Park, Gulf Islands National Seashore, and Cape Hatteras National Seashore, are all projected to experience sea level rise of over 0.69 m by 2100 (RCP8.5). This sea level rise, combined with storm surge, could be especially difficult for isolated island park units, such as the Caribbean park units, the National Park of American Samoa, and War in the Pacific National Historical Park, where access to aid in the event of a natural disaster may not be immediately available.
Conclusions

This report presents projections of sea level change (118 parks) and storm surge (79 parks) in coastal park units administered by the National Park Service. Sea level change and storm surge vary geographically, resulting in locally-specific challenges for adaptation and management. It is important to acknowledge that sea level change will affect some parts of Alaska differently than coastal parks in the rest of the country. Northwest Alaska can expect relative sea levels to increase over time; while in southeast Alaska, relative sea levels may continue to decrease over the first part of this century, followed by an increase in relative sea level towards the end of the century.

This project is an important first step in assessing how changes in sea level and storm surge may affect national park units. Using sea level rise and storm surge information, parks can begin to plan for effects on resources, facilities, access, and other areas of management. While methods used here are not appropriate for combining the separate sea level rise and storm surge results, parks should be aware of the potential for synergistic effects of sea level rise and storm surge causing impacts larger than either may cause individually. It is clear that more research can be done on these complex issues to assess how these changes may affect parks and regions. These data can inform future projects related to both natural and cultural resources as well as the planning and management of infrastructure.

Frequently Asked Questions

Q. How were the parks in this project selected?
   A. Parks were selected after consultation with regional managers. Regional managers were given a list of parks that authors considered to be vulnerable to sea level change and/or storm surge. This list was vetted by regional managers and their staff who added or subtracted park names based on their knowledge of the region.

Q. Who originally identified which park units should be used in this study?
   A. The initial list of parks was approved by the following regional managers: Northeast Region, Amanda Babson (signed 11/27/13); Southeast Region, Shawn Benge (signed 11/14/13); National Capital Region, Perry Wheelock (signed 3/17/14); Intermountain Region, Patrick Malone signed on behalf of Tammy Whittington (signed 11/13/13); Pacific West Region, Jay Goldsmith (signed 11/26/13); Alaska Region, Robert Winffree (signed 11/15/13).

Q. What’s the timeline of this project?
   A. This is the culmination of a three-year project that was proposed in February 2012. Initial Fiscal year of funding was 2013.

Q. In what instance did you use data from Tebaldi et al. (2012)?
   A. NOAA’s Sea Lake and Overland Surge from Hurricanes (SLOSH) model does not include storm surge predictions for all of the parks used in this study. We used data from Tebaldi et al. (2012) where reasonable to provide data for park units in California, Oregon, Washington, and southern Alaska. The following parks used Tebaldi et al. (2012) data: Cabrillo National Monument, Channel Islands National Park, Ebey’s Landing National Historical Reserve, Fort Point National Historic Site, Fort Vancouver National Historic Site, Golden Gate National Recreation Area, Klondike Gold Rush National Historical Park, Lewis and Clark National Historical Park, Olympic National Park, Port Chicago Naval Magazine National Scenic Trail, Point Reyes National Seashore, Redwood National Park, Rosie the Riveter WWII Home Front National Historical Park, San Francisco Maritime National Historical Park, San Juan Island National Historical Park, and Santa Monica Mountains National Recreation Area.

Q. Why don’t all of the parks have storm surge maps?
   A. Unfortunately some parks do not have enough data to complete a storm surge map. These were parks that were not modeled by NOAA’s SLOSH MOM model or near any of the tide gauges used by Tebaldi et al. (2012). These parks are: Aniakchak Preserve, Bering Land Bridge National Preserve, Cape Krusenstern National Monument, Glacier Bay National Park and Preserve, Katmai National Park, Kenai Fjords National Park, Lake Clark National Park, Sitka National Historical Park, War in the Pacific National Historical Park, and Wrangell – St. Elias National Park and Preserve.
Q. My park only has storm surge maps covering a few Saffir-Simpson categories. Why is that?
A. Some parks, particularly those in the Northeast Region, were not modeled by NOAA for the full range of Saffir-Simpson storm scenarios. This is because it is considered very unlikely that a Saffir-Simpson category 4 or 5 hurricane would be able to sustain itself into the northern latitudes of that region.

Q. Why are the storm surge maps in NAVD88?
A. That is the default datum for SLOSH data. This was a decision made by NOAA.

Q. What are the effects of NAVD88 on sea level and storm surge projections for some parks?
A. The North American Vertical Datum of 1988 (NAVD88) is a datum that is commonly used in North America to refer to the “elevation” of a location. It uses a fixed value for the height of North America’s mean sea level. While this is a popular datum for mapping, it has the limitation that it is based on the observed mean sea level for a single location: Rimouski, Canada. As you move further away from this location you can expect actual sea level to differ from the mean sea level at Rimouski. For locations such as California this can result in a significant difference between observed mean sea level and NAVD88. Your natural resource or GIS specialist will likely have further information about your specific location. Alternatively you can look up the differences in your region by checking the datum information for your nearest tide gauge station: https://tidesandcurrents.noaa.gov/stations.html?type=Datums

Q. Which sea level change or storm surge scenario would you recommend I use?
A. All parks are different, as are all projects. Your choice of scenario may depend on many different factors including risk tolerance and expected time horizon of the project. The NPS has not yet released any guidance on which climate change scenarios to use for planning. We would recommend you contact the appropriate project lead, natural or cultural resource manager, or someone from the Climate Change Response Program for further guidance depending on your situation.

Q. How accurate are these numbers?
A. The accuracy of these data varies depending on the data source. SLOSH data has +/- 20% accuracy, although this is discussed in greater detail by Glahn et al. (2009). Further information about storm surge data generated by Tebaldi et al. can be found in Tebaladi et al. (2012). IPCC global sea level rise projections range between 0.26 m (RCP2.6 minimum likely range) and 0.82 m (RCP8.5 maximum likely range) by 2100. The standard error of the IPCC is explained in greater detail in the Chapter 13 supplementary material in AR5 (IPCC 2013). An explanation on the horizontal and vertical accuracy of the digital elevation models used for mapping can be found in the metadata that accompanies the map data on www.irma.gov. DEM data were required to have a \( \leq 18.5 \) cm root mean square error vertical accuracy before they were converted to MHHW. An exception to this was in Alaska where these data were not available.
Q. We have had higher/lower storm surge numbers in the past. Why?
A. The numbers given here are meant to represent a maximum based on a typical storm surge category. As described above, there is likely to be some deviation around that number. Certain periods are also likely to result in higher than average storm surges. For example, periodic changes in regional water temperatures (caused by phenomena such as El Niño and La Niña) will impact water levels that will add to any storm surge. Likewise, changes in the North Atlantic Oscillation and Pacific Decadal Oscillation will also affect ocean conditions. This must be taken into account when using these numbers. All of these factors vary temporally and geographically, so contact your natural resource manager if you are unsure how this could impact your particular park unit.

Q. What other factors should I consider when looking at these numbers?
A. These projections do not include the impact of all man-made structures, such as flood barriers, levees, and dams. They also do not take into account how smaller features, such as dune systems or vegetation changes could impact coastal flooding. There are many meso- and micro-scale factors that need to be taken into account such as differences in topography, the presence/absence of any wetlands etc. It should also be expected that as sea levels change, areas of the shoreline will change accordingly, particularly due to erosion and accretion.

Q. Why don’t you recommend that I add storm surge numbers on top of the sea level change numbers?
A. Higher sea level and permanent inundation will change the way waves propagate within a basin. Sea level change is expected to have a significant impact on the geomorphology of the coastline. Changing water levels will lead to areas of greater erosion in some areas as well as increasing accretion in other places. As sea level changes, the fluid dynamics of a particular region will also change. For example, tidal distance will change as water levels rise, which will alter the spatial extent of a storm surge as well as potentially impacting wave height. This is not something NOAA takes into account in their SLOSH model.

Q. Where can I get more information about the sea level models used in this study?

Q. Where can I get more information about the NOAA SLOSH model?
A. http://www.nhc.noaa.gov/surge/slosh.php

Q. So, based on your maps, can I assume that my location will stay dry in the future?
A. No. As explained above, these numbers are accurate within a certain range. Also, these maps are based on “bathtub” models where water is simulated as rising over a static surface. In reality, your coastline will change in response to storms and other coastal dynamics. These numbers are intended for guidance only.
Q. Why do you use the period 1986–2005 as a baseline for your sea level rise projections?

A. We are following the standard approach used by the IPCC, USACE, and much of the academic literature. If you would like your estimate to start from a specific year you can do one of two things: 1) subtract the observed rate of sea level rise since 1992 for your location, or 2) contact park, region, or Climate Change Response Program staff for assistance. It may be possible to interpolate projections further to estimate the amount of rise the models estimate to have taken place between the baseline and whichever year you choose. We must caution that if you follow option 1 you will be introducing some inaccuracy to sea level projections, especially if you use data from a tide gauge that is not close to your location.

Q. The SLOSH/IPCC projections seem lower/higher than X source I’ve found. Why is that?

A. Projections can vary depending on a number of factors such as choice of model, approach, or the age of the study. We would recommend that you speak to a climate specialist when choosing sources.

Q. What are other impacts from sea level rise that parks should consider?

A. Impacts from sea level rise could include, but are not limited to, increased erosion, damaged cultural resources, damage to above and below ground infrastructure, difficulty accessing inundated infrastructure, increased groundwater intrusion, altered groundwater salinity, diminished space for recreational activities (possibly leading to conflict between different recreational users), and the complete loss or migration of certain coastal ecosystems. For more information on the topic, please see the Coastal Adaptation Strategies Handbook at: http://www.nps.gov/subjects/climatechange/coastalhandbook.htm
Appendix C

Waysides

The following pages show the final designs for waysides that were installed in parks as part of the funding for this project. Gulf Islands National Seashore received two waysides that were received in 2015. Jean Lafitte National Historical Park and Preserve and Fire Island National Seashores waysides were installed in 2016.
See Change...

The earth’s climate is changing, raising sea level and increasing the frequency of storm surges. Erosion and rising sea level change the shape and size of barrier islands and mainland shorelines along the Gulf Coast.

The roots of coastal plants slow erosion by anchoring the land. As sea level rises, increased salt content in the soil will kill the plants leaving the land exposed to more erosion. In many places, the amount of dry land is decreasing at a significant rate.

The Gulf Coast draws millions of visitors to relax in the bright sun, play in the crystal blue surf, explore the snow white beaches, and watch for wildlife. Yet, this dry land, at the edge of rising waters, could be claimed by the Gulf of Mexico forever.

Gulf Islands National Seashore is investing in energy efficient equipment and seeking new sustainable solutions to help keep these shores from disappearing beneath the rising sea.

Each year, erosion, storms, coastal development, and rising sea level shrink the nesting beach habitat of sea turtles. When a female sea turtle is ready to lay her eggs, she will try to return to the same sandy beach every two to three years. Will her nesting hole still be there?

Please join the National Park Service in protecting these beaches, so that you and your children may watch her hatchlings return to lay their eggs.

The road at Fort Pickens gets overwhelmed with storm waves. As the sea level rises, these events are becoming more common.
See Change...

The earth’s climate is changing, raising sea level and increasing the frequency of storm surges. Erosion and rising sea level change the shape and size of barrier islands and mainland shorelines along the Gulf Coast.

The roots of coastal plants slow erosion by anchoring the land. As sea level rises, increased salt content in the soil will kill the plants, leaving the land exposed to more erosion. In many places, the amount of dry land is decreasing at a significant rate.

Fighting the Rising Sea

Each year, erosion, storms, shipping channels, and rising sea level are changing the shoreline of the barrier islands. The National Park Service and Army Corps of Engineers work together on restoration projects to rebuild the coastline around historic forts. Massachusetts. The forts often featured by nature, putting the structure in jeopardy.

Please join the National Park Service in protecting our seashores, so that you and your children may continue to enjoy these historic places.

The Gulf Coast draws millions of visitors to relax in the bright sun, play in the crystal blue surf, explore the historic forts, and watch for wildlife. Yet, this dry land, at the edge of rising waters, could be claimed by the Gulf of Mexico forever.

Gulf Islands National Seashore is investing in energy-efficient equipment and seeking new sustainable solutions to help keep these shores from disappearing beneath the rising sea.
Sinking Land, Rising Water

This is the Barataria Basin, built of soil washed down this area by the Mississippi River. This soil is still compacting and sinking, a process called subsidence. Most of the Barataria Preserve is less than two feet above sea level, and its subsidence rate is nearly half an inch a year.

Meanwhile, glaciers and polar ice sheets are melting and our warming climate is heating oceans everywhere, making their waters expand just like water does when you heat it on the stove. Everywhere on the planet, the oceans are a little higher every day.

The combination of the Barataria Basin’s sinking land and global sea level rise means that the ocean is creeping in faster here than almost anywhere else in North America.

- Floods are becoming more frequent and lasting longer.
- Coastal wetlands are disappearing as land sinks and water rises.
- Less land is available to buffer Gulf of Mexico storms.
- Storm and flooding threats to homes, communities, and infrastructure like highways, ports, and energy facilities are increasing.
- Salt water from the Gulf is moving into freshwater wetlands, killing the plants that hold the land together.
- Death of plants, animals, and micro-organisms that cannot tolerate increased flooding or salt water.
See Change In A Changing Climate

Natural landscape change can be nearly imperceptible on a barrier island, as the wind and waves gradually shape the shoreline, beach, and dunes. Natural changes can also be obvious and happen quickly during storms like hurricanes and nor’easters. Looking ahead, storms will have a greater impact on Fire Island due to climate change.

When we burn fossil fuels, carbon dioxide is released into the atmosphere and acts like a heat trapping blanket around our planet. Heat that would normally escape from the atmosphere is retained, warming the Earth, and changing climate patterns. As ocean waters warm and ice on land melts, sea level rises and impacts Fire Island and coastlines all over the world. The future of this barrier island is in jeopardy due to these human-induced climate change effects.

Fire Island protects mainland Long Island against storms and is a stunning setting for recreation, education, and inspiration. It also provides critical habitat for plants and wildlife. We must do what we can to protect this special place. By using renewable energy sources and reducing our dependence on fossil fuels, we can take steps today to preserve barrier island systems and processes, and help build natural resilience to future storms and sea-level rise.

Storm Stories

On October 29, 2012, Hurricane Sandy struck Fire Island National Seashore and changed the lay of the land. During the storm high water and large waves scoured sand from the beach and dunes, moved sand across the width of the island, and carved the breach, pictured here, through the barrier island. The storm was the strongest in recorded history to make landfall in this region.

To learn more about how climate change is impacting the Seashore, please visit www.nps.gov/fiis/learn/climatechange.htm

Hey Patrick,

Be aware that review is still in process. Once we have a final version, we will definitely get it to all authors for their concurrence.

More soon,

L

Hi Rebecca,

The SharePoint link is not working from my network connection. When you have a moment, may you please e-mail me the file or post it on Google Drive if it the file size is too large. Also, perhaps you have already sent it to Maria Caffrey, but she, the lead author, is not on the e-mail below.

Cat had mentioned that further edits might be made and I wish to see the final text since Maria has included me as an author.

Thanks,

Patrick

Principal Climate Change Scientist
Natural Resource Stewardship and Science
Hello Larry, Rebecca, everyone.

For most reports, all of the steps below are completed within 2-10 working days of us sending the (this) final review email.

Let's quickly publish it and make it public before someone decides to delay or stop publication again!

**Three Remaining Steps**
*(Download detailed instructions for all three steps)*

**Step 1. Click on the link below to open the document directly on the SharePoint site:**

The online Manuscript Submittal Form for this report can be seen at:

Step 2. Double-check and approve my updates (Larry and Rebecca).

a) Make your absolute final edits (if any), and send the final result back to me to make a final PDF.

You can change anything you like between the table of Appendices and the inside back cover.

b) I will send the final PDF back to you for one final check before I do the 508 tagging and upload it to IRMA.

Make sure that you can live with everything in the final PDF before I Section 508 tagging.

It takes me about 2 minutes per page to remediate the tags in a document of this size (about 184 minutes, or 3 hours).

Any changes after that point means creates a brand new document, and requires me to repeat the 508 tagging once again (another 3 hours of work).

Step 3. Activate the draft IRMA record that I created for you (Larry or Fagan?).

a) Go to this address to open the draft Data Store record that I created for you:

https://irma.nps.gov/DataStore/Reference/Profile/2249974

b) Click the Actions drop down menu near the top right of the screen and click Edit and update the Core and Subjects and Keywords information as you desire

Note: Search engines can only search on the information that you enter on these screens, and cannot search any uploaded PDF files.

c) Go to the Files and Links tab. On the Add drop down menu, choose the Digital File. Use the file upload tools to upload the final PDF.

d) To make the Data Store record public, click the Activate button at
That's it!

Hi Elizabeth!

Great to hear from you again. Congratulations on the new position!

I’m still at the moment and so I’m not entirely sure on the latest information regarding the report. I don’t, so I don’t have access to my federal email until I’m in the office to catch up.

I’m copying Larry Perez on this email. He is the head of communications for the NPS climate response program. I left the report with his team before I took off so he will have the most up to date information on the status of the report.

Cheers

Maria Caffrey, Ph.D.

Hi Maria,

I see from your twitter feed that you recently... Congratulations!

We spoke when I was at NPR and High Country News. I’m starting a new job as a science reporter for Reveal from the Center for Investigative Reporting. Now that the scope of my job is nationwide, I’d be eager to talk with you more about some of your findings about sea—level rise in parks.

I start my job on Monday, so it would be great to speak with you early next week if you have time in your schedule. Do you have a draft report that I could read? Thanks much,

Elizabeth Shogren

Hello, Elizabeth.

Thanks for your interest in the forthcoming sea level rise and storm surge report. The report is currently undergoing internal review and we do not yet have a definitive publication date.

As you might understand, we will not be sharing any drafts prior to publication.

Best,

Larry

U.S. Department of the Interior
National Park Service
Natural Resource Stewardship and Science
Fort Collins, Colorado
The National Park Service, Natural Resource Stewardship and Science office in Fort Collins, Colorado, publishes a range of reports that address natural resource topics. These reports are of interest and applicability to a broad audience in the National Park Service and others in natural resource management, including scientists, conservation and environmental constituencies, and the public.

The Natural Resource Report Series is used to disseminate comprehensive information and analysis about natural resources and related topics concerning lands managed by the National Park Service. The series supports the advancement of science, informed decision-making, and the achievement of the National Park Service mission. The series also provides a forum for presenting more lengthy results that may not be accepted by publications with page limitations.

All manuscripts in the series receive the appropriate level of peer review to ensure that the information is scientifically credible, technically accurate, appropriately written for the intended audience, and designed and published in a professional manner.

This report received formal peer review by subject-matter experts who were not directly involved in the collection, analysis, or reporting of the data, and whose background and expertise put them on par technically and scientifically with the authors of the information.

Views, statements, findings, conclusions, recommendations, and data in this report do not necessarily reflect views and policies of the National Park Service, U.S. Department of the Interior. Mention of trade names or commercial products does not constitute endorsement or recommendation for use by the U.S. Government.

This report is available in digital format from the Climate Change Response Program website and the Natural Resource Publications Management website. To receive this report in a format optimized for screen readers, please email irma@nps.gov.

Figures

**Figure 1.** Sea level trends for the United States based on Zervas (2009), for all available data through 2015. Each dot represents the location of a long-term (>30 years) tide gauge station. Green dots represent stations that are experiencing the average global rate of sea level change. Stations depicted by yellow to red dots are experiencing greater than the global average (primarily driven by regional subsidence) and blue to purple dots are stations experiencing less than the global average (due to isostatic rebound or other tectonically-driven factors). Source: https://tidesandcurrents.noaa.gov/sltrends/slrmap.htm .......................................................... 3

**Figure 2.** An example of how areas of inundation appear in ArcGIS. In this example for the Toms Cove area of Assateague Island National Seashore, areas of inundation (RCP4.5 2050) appear in blue. Green shading indicates other low lying areas that are blocked from inundation by some impediment, but nonetheless could experience flooding should the physical barrier be removed or breached. ............................................................................. 7

**Figure 3.** An example of the extent of an operational basin shown in NOAA’s SLOSH display program (http://www.nhc.noaa.gov/surge/slosh.php). The black area is the full extent of the operational basin for Chesapeake Bay .............................................................................. 8

**Figure 4.** Projected future sea level by NPS region for 2100 under RCP8.5 (the “business as usual” climate change scenario). Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each region ........................................ 13

**Figure 5.** Projected future sea level rise by NPS region for 2030 under RCP8.5 (the “business as usual” climate change scenario). Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each region ........................................ 14

**Figure 6.** Projected future sea level rise by NPS region for 2050 under RCP8.5 (the “business as usual” climate change scenario). Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each region ........................................ 15

**Figure 7.** Projected future sea level rise by 2100 for the NPS Northeast Region under all of the representative concentration pathways. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each category ........................................................................................................ 16

**Figure 8.** Estimated storm surge created by Saffir-Simpson category 3 hurricane occurring at high tide near Boston Harbor Islands National Recreation Area. Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range). ............................................................................. 17
Figure 9. SLOSH MOM storm surge maps for a Saffir-Simpson category 1 (left) versus category 2 hurricane striking Everglades National Park at mean tide (right). Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range). .......................................................... 19

Figure 10. A SLOSH MOM map showing storm surge height and extent created by a Saffir-Simpson category 2 hurricane striking the Washington D.C. region at high tide. Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range). .......................................................... 20

Figure 11. Projected future sea level rise by 2100 for the NPS Intermountain Region under all of the representative concentration pathways. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation from each mean. Blue bars mark the full range of sea level estimates for each category.................................................................................................................................. 22

Figure 12. A SLOSH MOM map showing storm surge height and extent created by a Saffir-Simpson category 4 hurricane striking the southwestern Texas region at mean tide. The dark green line around the island represents the boundary of Padre Island National Seashore. Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range)........................................................... 23

Figure 13. Radiative forcing for each of the Representative Concentration Pathways (RCPs). An increase in radiative forcing (due to the loading of anthropogenic gases into the atmosphere) will result in higher global average temperatures. RCPs replace the IPCC SRES scenarios. Note how RCP4.5 (yellow line) projections are slightly higher than RCP6.0 (gray line) in the early part of this century. Source: Meinshausen et al. 2011. ......................... 26

Executive Summary

**Comment 1** Changing relative sea levels and the potential for increasing storm surges due to anthropogenic climate change present challenges to national park managers. This report summarizes work done by the University of Colorado in partnership with the National Park Service (NPS) to provide sea level rise and storm surge projections to coastal area national parks using information from the United Nations Intergovernmental Panel on Climate Change (IPCC) and storm surge scenarios from National Oceanic and Atmospheric Administration (NOAA) models. This research is the first to analyze IPCC and NOAA projections of sea level and storm surge under climate change for U.S. national parks. Results illustrate potential future inundation and storm surge due to climate change under four greenhouse gas emissions scenarios. In addition to including multiple scenarios, the analysis considers multiple time horizons (2030, 2050 and 2100). This analysis provides sea level rise projections for 118 park units and storm surge projections for 79 of those parks.

Within the National Park Service, the National Capital Region is projected to experience the highest average rate of sea level change by 2100. The coastline adjacent to Wright Brothers National Memorial in the Southeast Region is projected to experience the highest sea level rise by 2100. The Southeast Region is projected to experience the highest storm surges based on historical data and NOAA storm surge models.

**Comment 2** These results are intended to inform park planning and adaptation strategies for resources managed by the National Park Service.

Acknowledgments

This project was awarded funds through the NPS Servicewide Comprehensive Call (FY2013–2015) and augmented by funds from the Natural Resource Stewardship and Science Directorate’s Geologic Resources Division and Climate Change Response Program. We would like to thank the members of the communication advisory team (Rebecca Beavers, Lynda Bell, Maria Caffrey, Janet Cakir, Will Elder, Stanton Enomoto, Ann Gallagher, Matt Holly, Shawn Norton, Larry Perez, and Ryan Stubblebine) and science advisory team (Amanda Babson, Rebecca Beavers, Maria Caffrey, Patrick Gonzalez, Steve Nerem, and Rob Thieler) for their time and input into this project.

We would also like to thank Susan Teel and Caroline Rohe at Gulf Islands National Seashore for assistance in designing two wayside exhibits. Likewise, we thank Julie Whitbeck, Aleutia Scott, Kristy Wallisch, and Stacy Meyers for helping design, review, and install a wayside at Jean Lafitte National Historical Park and Preserve. Elizabeth Rogers and Kathy Krause helped design a wayside for Fire Island National Seashore. Doug Wilder, Dorothy Friday, and Neal Jander designed the online map viewer. We would also like to thank Jason Kenworthy, Rebecca Port, Michael Barthelmes, Bob Glahn, Doug Marcy, Chris Zervas, and Claudia Tebaldi for their assistance in editing and reviewing this document. Finally, we thank the National Oceanic and Atmospheric Administration for and the Intergovernmental Panel on Climate Change for providing the respective storm surge and sea level rise data cited throughout this document.

List of Terms

The following list of terms are defined here as they will be used in this report.

Bathtub model: A simplification of the sea as bathtub of water to simulate a change in water level relative to the land. This model does not include other factors such changes in erosion or accretion that change alter the geometry of the coastline.

Flooding: The temporary occurrence of water on the land.

Inundation: The permanent impoundment of water on what had previously been dry land.

Isostatic rebound: A change in land level caused by a change in loadings on the Earth’s crust. The most common cause of isostatic rebound is the loading of continental ice during the Last Glacial Maximum in North America. The North American land surface is still returning to equilibrium after the melting of this continental ice in an effort to return to equilibrium with its original pre-loading state.

National Park Service unit: Property owned or managed by the National Park Service.

Relative sea level: Where the water level can be found compared to some reference point on land. This term is most frequently used in discussion of changes in relative sea level. A change in relative sea level could be caused by a change in water volume or a change in land level (or some combination of these two factors).
Sea level: The average level of the seawater surface.

Sea level change: This term is frequently used in reference to relative sea level change. This is the product of two main factors, 1) an increase in the volume of ocean water, and 2) a change in land level. These two factors can be broken down further into other drivers that will be discussed in greater detail in other sections. This term is sometimes mistakenly confused with the term sea level rise.

Sea level rise: An increase in sea level. This is the result of an increase in ocean water volume caused principally by melting continental ice and thermal expansion. This term is not to be confused with increasing relative sea level, which can also be caused by decreasing land levels.
**Introduction**

**Comment 3** Global sea level is rising. While sea levels have been gradually rising since the last glacial maximum approximately 21,000 years ago (Clark et al. 2009, Lambeck et al. 2014), anthropogenic climate change has significantly increased the rate of global sea level rise (Grinsted et al. 2010, Church and White 2011, Slangen et al. 2016, Fasullo et al. 2016). Human activities continue to release carbon dioxide (CO2) into the atmosphere, causing the Earth’s atmosphere to warm (IPCC 2013, Mearns et al. 2013, Melillo et al. 2014). Continued warming of the atmosphere will cause sea levels to continue to rise, which will have a significant impact on how we protect and manage our public lands. The rate of warming depends on numerous factors considered by the Intergovernmental Panel on Climate Change (IPCC) under four different representative concentration pathways (RCPs; Moss et al. 2010, Meinshausen et al. 2011). Used as the basis for this report, the RCPs are climate change scenarios based on potential greenhouse gas concentration trajectories introduced in the fifth climate change assessment report of the Intergovernmental Panel on Climate Change (IPCC 2013). The IPCC’s process-based approach for estimating future sea levels contrasts with other estimates from semi-empirical techniques that commonly generate higher numbers.

This report provides estimates of sea level change due to climate change for 118 National Park Service units and estimates of storm surge for 79 of those units. As temperature increases, sea levels rise due to a number of factors that will be discussed in greater detail. As sea levels incrementally rise, periods of flooding caused by storms and hurricanes exacerbate the growing problem of coastal inundation (see list of terms). **Comment 4** Peek et al. (2015) estimated that the cost of sea level rise in 40 National Park Service units could exceed $40 billion if these units were exposed to one-meter of sea level rise. The aim of this report is to: 1) quantify projections of sea level rise over the next century based on the latest IPCC (2013) models, and 2) show how storm surge generated by hurricanes and extratropical storms could also affect these parks.

When Hurricane Sandy struck New York City in 2012 it caused an estimated $19 billion in damage to public and private infrastructure (Tollefson 2013). **Comment 5** This single storm cannot be attributed to anthropogenic climate change, but the storm surge occurred over a sea whose level had risen due to climate change. Extreme storms such as Hurricane Sandy have extreme costs. When Hurricane Sandy struck it was estimated to have a return period between a 398 year (Lin et al. 2016) and a 1570 year storm (Sweet et al. 2013). Currently, a 100 year storm surge in New York City could cost $2\(-5 billion and a 500 year storm surge could cost $5\(-11 billion (Aerts et al. 2013). **Comment 5, contd.** Under future scenarios of increasing anthropogenic greenhouse gas emissions, models project increasing storm intensities (Mann and Emanuel 2006, Knutson et al. 2010, Lin et al. 2012, Ting et al. 2015). When this change in storm intensity (and therefore, storm surge) is combined with sea level rise, we expect to see increased coastal flooding and the permanent loss of land across much of the United States coastline. Increasing sea levels increase the likelihood of another Hurricane Sandy-sized storm surge striking New York City. Factoring in future sea level rise to these estimates reduces the potential return interval of a similar storm surge occurring by 2100 to between 50 years (Sweet et al. 2013) and 90 years (Lin et al. 2016).
Format of This Report
This report contains five sections (introduction, methods, results, discussion, and conclusion), and presents results per park alphabetically by region. The 118 park units studied for this project cover six administrative regions: the Northeast, Southeast, National Capital, Intermountain, Pacific West, and Alaska. The scope of this project focuses on sea levels. The scope of this project did not include projected changes in lake levels, although interior waterways and lakes, especially the Great Lakes, are vulnerable to the effects of climate change. Further explanation on how to access the data from this project is available in the methods sections and accompanying appendices.

Frequently Used Terms
Definitions of the most basic terms used in this report occur on page ix. However, some terms require greater explanation for their use. For example, we follow the advice of Flick et al. (2012) in differentiating between the terms flooding and inundation. While many choose to use these terms interchangeably, we use the term “flooding” to describe the temporary impoundment of water on land. This usually results from storm activity and other short-lived events, such as periodic tidal action, and will therefore be used here in reference to the effects of a storm surge on land. “Inundation” is used to refer to the gradual permanent submergence of land that will occur due to sea level rise.

The terms sea level rise and sea level change are also used differently. Sea level rise refers only to rising water levels resulting from an increase in global ocean volumes. In most parts of the United States this increase in water volume will lead to increasing relative sea levels. However, in some parts of the country relative sea level is decreasing due to isostatic rebound. Figure 1 shows current sea level trends based on tide gauge records for United States that span at least 30-years of data.

For example, the Southeast Region of Alaska is experiencing a decrease in relative sea level. Alaska’s crust continues to rebound following the melting of large volumes of ice that occurred for centuries to millennia on land in the form of glaciers and ice fields. Alaska is tectonically complex with extensive faults that contribute to this crustal motion. Although the volume of ocean water in this region is increasing, the rate of sea level rise is less than the rate of isostatic rebound, resulting in a decrease in relative sea level. For this reason, we use the term “sea level change” as it includes regions that will experience a decrease in relative sea level (at least in the early part of this century) as well as those that will see increasing relative sea levels.
Figure 1. Sea level trends for the United States based on Zervas (2009), for all available data through 2015. Each dot represents the location of a long-term (>30 years) tide gauge station. Green dots represent stations that are experiencing the average global rate of sea level change. Stations depicted by yellow to red dots are experiencing greater than the global average (primarily driven by regional subsidence) and blue to purple dots are stations experiencing less than the global average (due to isostatic rebound or other tectonically-driven factors). Methods

This report summarizes work of a three-year project initiated in 2013, analyzing sea level change in 118 National Park Service units. Consultation with regional managers regarding units they considered to be potentially vulnerable to sea level change and/or storm surge resulted in selection of these 118 coastal park units (Appendix B). Project activities included the following:

1) Prepare sea level projections over multiple time horizons for each park unit.
2) Estimate potential exposure to storm surge using the National Oceanographic and Atmospheric Administration (NOAA) Sea, Lake, and Overland Surge from Hurricanes (SLOSH) Model and Tebaldi et al. (2012).
3) Create wayside exhibits1 with information about the impacts of climate change in the coastal zone for three National Park Service units.

Based on recommendations from regional personnel, three National Park Service units were selected as sites for wayside exhibits: Gulf Islands National Seashore, Jean Lafitte National Historical Park and Preserve, and Fire Island National Seashore. The finished wayside designs are in Appendix C. Each design is different, customized to reflect the messaging and/or themes of each unit.

Sea Level Rise Data

Comment 6 Sea level rise is caused by numerous factors. As human activities release CO2 and other greenhouse gases into the atmosphere, mean global temperatures increase (IPCC 2013, Gillett et al. 2013, Frölicher et al. 2014). Rising global temperatures cause ice located on land and in the sea to melt. The melting of ice found on land, such as Greenland and Antarctica, is a significant driver of sea level rise.

While the melting of sea ice is problematic from an oceanographic and heat budget perspective (primarily because it alters water temperatures and salinity and also because it changes the reflectance of solar energy from the surface), melting sea ice does not cause sea level rise. It is the melting of ice that is currently stored on land that raises global sea levels. Water level does not change when sea ice (ice wholly supported by water) melts. The volume of water in the sea remains the same whether it is frozen or liquid. The phase shift of water from solid to liquid does not displace an additional volume of water.

As ocean waters warm, the density of these waters also changes, causing thermal expansion. Thermal expansion was responsible for two-fifths of sea level rise from 1993 to 2010, while melting ice accounted for half (IPCC 2013). Table 1 lists the contribution to sea level rise from several key sources.

1 A wayside is an exhibit designed to be installed outside for visitors to learn about a particular subject (https://www.nps.gov/hfc/products/waysides/).

aData until 2009, not 2010.
bThis is not included in the total because these numbers have already been included in the Greenland ice sheet.
cThis is calculated as observed global mean sea level rise – modeled glaciers – observed land water storage. See table 13.1 in IPCC (2013) for more details.

The IPCC sea level rise projections used in this analysis follow a process-based model approach, which estimates sea level based on the underlying physical processes. This contrasts with semi-empirical models that combine past sea level observations with other variables or theoretical considerations, including, in some cases, expert opinion (surveys or interviews of professionals) (Rahmstorf 2010, Orlic and Pasaric 2013). Often the semi-empirical approach yields higher sea level estimates. IPCC (2013) uses coupled atmosphere-ocean general circulation models (AOGCMs) to simulate the processes of change rather than the statistical inferences of the semi-empirical approach. AOGCMs are considered a process-based technique, although some variables derive from semi-empirical methods (IPCC 2013).

Sea level rise estimates for 2050 and 2100 were taken directly from the IPCC (2013) regional climate models (RCMs) downscaled to a spatial grid resolution of 1˚ x 1˚ from AOGCMs. Because many park units require estimates for shorter time horizons that fit more closely with the expected lifetime of various projects, sea level rise projections for 2030 were calculated using IPCC RCM data for each sea level rise driver shown in Table 2, interpolated to 2030 for each RCP. All projections are reported relative to the period 1986–2005 (see Appendix B for further discussion). All geographic information systems (GIS) maps display the projected sea level on top of mean higher-high water (MHHW) using the most recent tidal datum epoch (1983–2001). MHHW is calculated by averaging the highest daily water level over a 19-year tidal datum epoch.

<sup>a</sup>Changes in ice mass derived through direct observation and satellite data.

The standard error (\(\sigma\)) for each site estimate was not calculated because it was beyond the scope of this project. However, it can be calculated using the following equation and data available from the IPCC (2013, supplementary material):

\[
\sigma^2 = \sigma_{st}^2 + \sigma_{smb_a}^2 + \sigma_{smb_g}^2 + \sigma_{glac}^2 + \sigma_{IBE}^2 + \sigma_{GIA}^2 + \sigma_{LW}^2 + \sigma_{dyn_a}^2 + \sigma_{dyn_g}^2
\]

Where: \(\sigma_{st}\) = the global thermal expansion uncertainty plus dynamic sea surface height; \(\sigma_{smb_a}\) = the Antarctic ice sheet surface mass balance uncertainty; \(\sigma_{smb_g}\) = the Greenland ice sheet surface mass balance uncertainty; \(\sigma_{glac}\) = glacier uncertainty; \(\sigma_{IBE}\) = the inverse barometer effect uncertainty; \(\sigma_{GIA}\) = global isostatic adjustment; \(\sigma_{LW}\) = the land water uncertainty; \(\sigma_{dyn_a}\) = Antarctica ice sheet rapid dynamics uncertainty; and, \(\sigma_{dyn_g}\) = Greenland ice sheet rapid dynamics uncertainty.

Initial data were exported as GeoTIFF files for use in ArcGIS. For parks that crossed more than one pixel, an average sea level rise was calculated by weighting pixel values by the length of park shoreline in each pixel. A standard bathtub model approach was used to identify areas of projected inundation and flooding. In this method, projected sea level under climate change was determined by adding the IPCC RCM value to the current mean higher high water level. The land that would be at or below a projected sea level was then determined by analyzing digital elevation models (DEMs) of land elevation at spatial resolutions of 500 to 7000 m, depending on data availability for the areas of each park. DEM data for most regions were gathered from the NOAA digital coast website (https://coast.noaa.gov/digitalcoast). Areas of inundation and flooding are denoted in the maps (Appendix A) in blue. Additional low-lying areas that could be potentially inundated or flooded are shown in green (Figure 2). These low-lying areas do not appear to have any inlet or other pathway for water (based on our elevation datasets), although they should still be considered vulnerable to exposure to either groundwater seepage or potential flooding via breaching. The lack of high-resolution DEMs and time constraints prevented us from attempting a dynamic modeling approach (see limitations below). Maps were created to illustrate inundation for all park units for 2050 and...
2100 under RCP4.5 and RCP8.5. These two represent a plausible range of scenarios between significant policy response (RCP4.5) and business as usual (RCP8.5).

Figure 2. An example of how areas of inundation appear in ArcGIS. In this example for the Toms Cove area of Assateague Island National Seashore, areas of inundation (RCP4.5 2050) appear in blue. Green shading indicates other low lying areas that are blocked from inundation by some impediment, but nonetheless could experience flooding should the physical barrier be removed or breached.

Storm Surge Data
NOAA SLOSH data estimate potential storm surge height at current (most recent tidal datum) sea level (NOAA 2016). The NOAA SLOSH model comprises the following three products (P-Surge, MEOW, and MOMs) that utilize three different modeling approaches (probabilistic, deterministic, and composite) to estimate storm surge.

P-Surge (also known as the tropical cyclone storm surge probabilities product) uses a probabilistic approach by examining past events to estimate the storm surge generated by a cyclone that is present and within 72-hours of landfall. It statistically evaluates National Hurricane Center data (calculated in part using a deterministic approach) including the official projected cyclone track and historical forecasting errors. It also incorporates astronomical tide calculations and variations in the radius of
maximum wind into this estimate. These rates of motion variables are then fit to a Cartesian or polar (depending on the location) grid (Jalesnianski et al. 1992).

The Maximum Envelope Of Water (MEOW) calculates flooding using past SLOSH output to create a composite estimate of the potential storm surge generated by a hypothetical storm. This product generates a worst-case scenario based on a hypothetical storm category that includes forward speed, trajectory of the storm when it strikes the coastline, and initial (mean vs. high) tide level that will also incorporate any historical uncertainty from previous landfall forecasts.

The final SLOSH product is the MOM (Maximum of MEOWs) model. MOM is a further composite approach that uses the forward speed, trajectory, and initial tide level data that is also used by MEOW to create a worst-of-the-worst scenario (or “perfect storm”). Storms are simulated for 32 regions (also known as operational basins, Figure 3) defined by NOAA. Data was imported into ArcGIS using the SLOSH display program. Maps were generated showing storm surge for all possible Saffir-Simpson hurricane categories for each site. While most sites had data for Saffir-Simpson hurricane categories 1–5 (Table 3), a few sites, such as Acadia National Park, were missing the highest category. NOAA did not model this scenario because it is considered extremely unlikely at a location that far north in the Atlantic Ocean.

Figure 3. An example of the extent of an operational basin shown in NOAA’s SLOSH display program (http://www.nhc.noaa.gov/surge/slosh.php). The black area is the full extent of the operational basin for Chesapeake Bay.

SLOSH MOM was used to estimate potential storm surge in 79 coastal park units. Unfortunately, MOM data do not exist for the remaining 39 units, so we supplemented this with data from Tebaldi et al. (2012) wherever possible. Tebaldi et al. (2012) used 55 long-term tide gauge records to calculate potential sea level and storm surge estimates above mean high water levels. We used the current 50-year and 100-yr return level data from their paper for any parks near a tide gauge. Unfortunately, due to insufficient coverage by tide gauges in this area, we were unable to use either Tebaldi et al. (2012) or SLOSH MOM data for the Alaska, Guam, and American Samoa park units. It is important to note that the Tebaldi (2012) and SLOSH MOM data differ in their methods of calculation making it inadvisable to compare storm surge values from the Pacific West Region to other regions. However, this method had to be used due to the lack of SLOSH MOM data for the Pacific West Region.

We recommend that parks planning for future hurricanes use information from one hurricane category higher than any previous storm experienced. Historical hurricane data from the International Best Track Archive for Climate Stewardship (IBTrACS; Knapp et al. 2010) is listed in Appendix D (Table D3) to allow staff to determine the highest Saffir-Simpson category hurricane to strike within 10 miles of each park unit. Applying information from one storm category higher than historical data may more closely approximate what could happen in the future, as storms are projected to be more intense under continued climate change (Emanuel 2005, Webster et al. 2005, Mendelsohn et al. 2012). However, we recommend caution in using this approach for any detailed (site-level) planning due to limitations discussed in the following section of this report.

Limitations
All projects of this nature have limitations that should be clearly described to ensure appropriate use and interpretation of these data.

Every effort has been made to incorporate any parks established after this project began (e.g. Harriet Tubman Underground Railroad National Monument); however, some maps might be missing due to lack of available boundary data in new units.

Sea level and storm surge estimates were derived using separate programs from the IPCC and NOAA, respectively. These numbers were then imported into GIS maps using the program ArcGIS. We used a bathtub modeling approach to map the extent of sea level rise and storm surge over every unit. Bathtub modeling simply simulates how high or how far inland water will go under different
climate change scenarios. It does not recognize changes in topography or other environmental or artificial systems that may exist or occur in response to encroaching water. Although the bathtub model is the most widely used technique for modeling inundation, it is also a simplistic approach to simulating how sea level rise will affect a landscape (Storlazzi et al. 2013). Dynamic models could simulate changes in flow around buildings or estimate how topographic features such as dune systems may migrate in response to inundation and flooding, but dynamic models also vary, which can be a severe limitation in trying to standardize data for summary analysis and comparison.

The maps provided through this analysis vary in horizontal and vertical accuracy depending on which digital elevation model (DEM) data were available at the time of mapping. This is discussed in more detail in the metadata that accompany each map. DEM data for most regions were gathered from the NOAA digital coast website (https://coast.noaa.gov/digitalcoast/) which uses source elevation data that either meet or exceed current Federal Emergency Management mapping specifications. These NOAA digital coast data were required to have a minimum root mean square error of 18.5 cm for low lying areas that were then corrected for MHHW using the NOAA VDatum model (Parker et al. 2003). USGS data were used for areas, such as Alaska, where digital coastal data were not available. We recommend referring to Schmid et al. (2014) for further discussion on potential uncertainty of this technique.

Although SLOSH MOM has the widest geographic storm surge coverage of any model in the US, storm surge data were not available for every part of the coastline. Every effort has been made by this project to bridge any gaps where SLOSH MOM does not exist. While the Tebaldi et al. (2012) data cover the California, Oregon, Washington, and southern Alaskan coastlines, they do not cover northern Alaskan, American Samoan, or Guam coastlines. These coastlines are vulnerable to storm surge but we could not find data that satisfied our standards of accuracy sufficiently to be included in our mapping efforts.

Furthermore, storm surge maps are only intended as a rough guide of how flooding caused by storm surge will look today. As more of the coastline becomes inundated we can expect coastal flooding patterns to also change accordingly. The SLOSH model is a multiple scenario approach that uses previous storms to estimate future storm surge. It cannot take into account changes in future basin morphology that could affect the fluid dynamics and propagation of coastal flooding.

SLOSH MOM is modeled using mean sea level (0 m NAVD88) and what NOAA terms “high tide” (which is not tied to the local tidal datum, but is actually a round number based on the modeled average high tide for the region). Jalesnianski et al. (1992) estimate surge estimates to be accurate +/- 20%, although Glahn et al. (2009) discuss how others have found the P-Surge model to be more accurate than originally estimated. Such factors must be kept in mind when using these numbers for mapping.

**Land Level Change**

It is important to include changes in land level while interpreting changes in sea level. The IPCC (2013) includes a limited amount of data regarding changes in relative sea level in their calculations of sea level change. Our sea level rise results include the IPCC estimates of how changes in land
level will change over time based on estimates of glacial isostatic adjustment. Land level change is an important variable when calculating relative sea level. Land levels have changed over time in response to numerous factors. Changes in various land-based loadings—such as ice sheets during the last glacial maximum—has been a significant cause of land level change in the U.S. Post-glacial isostatic rebound is the result of this pressure being released after the removal of ice sheets on the Earth’s crust. Land level can also be altered by other factors such as tectonic shifts, particularly along the Alaska and continental U.S. Pacific coastlines. These drivers can often prompt a relative increase or decrease in land level depending on location. Other factors such as aquifer drawdown and the draining of coastal swamps can create decreases in relative land level.

Quantifying how land levels are changing is difficult given the paucity of data available prior to modern satellite data. An upcoming NASA publication on land-based movement (Nerem pers. comm.) will help to address this data need, providing numbers for land-based movement across the country. Data from the NASA report can then be incorporated with sea level rise numbers from this analysis using the following equation (after Lentz et al. 2016):

\[ a_e = E_0 - e_i + R \]

Where; \( a_e \) is the adjusted elevation, \( E_0 \) is the initial land elevation, \( e_i \) is the future sea level for either 2030, 2050, or 2100, and \( R \) is the current rate of land movement over time due to isostatic adjustments.

In the interim, tide gauges can provide further data regarding changes in land level, but should be used cautiously. We have listed tide gauge data for the rate of change in land level for tide gauges nearest to all units for this study in Appendix D; however, only Fort Pulaski National Monument and Golden Gate National Recreation Area have a long-term tide gauge on site. This lack of nearby long-term data can limit the accuracy of these numbers if they are applied to sea level change projections for almost all other parks units. We indicate in Table D1 which of the nearest tide gauges we do not recommend using to estimate land movement. This is because in many case the boundary of the park unit is located either too far away or on a different land mass to where the nearest tide gauge is, which increases the inaccuracy of this data. Land level changes were only reported for long-term tide gauges that had at least thirty years of data in order to ensure a statistically robust dataset. Based on these limited records, we estimate that seven park units are currently experiencing decreasing relative sea levels (Glacier Bay National Park, Glacier Bay Preserve, Katmai National Park, Kenai Fjords National Park, Lake Clark National Park, Sitka National Historical Park), although we cannot be certain of this number given that many of the park units are some distance from a tide gauge. We expect the release of the NASA data (Nerem pers. comm.) to help refine these estimates.

A discussion of the applicability of these land level numbers (with a natural resources manager or similar expert) should accompany use of individual park maps from this analysis to ensure that the nearest tide gauge to any particular project site is appropriate. Current rates of subsidence at these tide gauges range between +7.6 mm/y (Grand Isle, Louisiana) and -19 mm/y (Skagway, Alaska; Table D1). In selecting an appropriate tide gauge to use, variables including oceanographic setting, length of the record, completeness of data, and geography of the coastline must be considered. The
science team for this project decided against setting a threshold for how close a park unit should be to a long-term tide gauge based on considerations discussed above.

**Where to Access the Data**

All GIS data from this project are available at [https://irma.nps.gov/Portal](https://irma.nps.gov/Portal) for archiving by park.

A website discussing this project is available at the following address: [https://www.nps.gov/subjects/climatechange/sealevelchange.htm](https://www.nps.gov/subjects/climatechange/sealevelchange.htm)

The raw IPCC (2013) data can be downloaded using the following link: [http://www.ipcc.ch/report/ar5/wg1/docs/ar5_wg1_ch13sm_datafiles.zip](http://www.ipcc.ch/report/ar5/wg1/docs/ar5_wg1_ch13sm_datafiles.zip)
Results

Sea level and storm surge maps are in Appendix A. A full list of the 118 park units and a table listing sea level projections by park are available in Appendix D. Following the methods outlined above, we found that sea level rise projections across the 118 park units average between 0.45 m (RCP2.6) and 0.67 m (RCP8.5) by 2100. However, this number masks how these projections will vary geographically. Figure 4 shows these projections in more detail and provides sea level estimates by region. Error bars in Figure 4 denote the standard deviation for each average per region, further revealing how these numbers can vary. A high standard deviation and range signals that sea level estimates vary between units within regions, whereas a low standard deviation and small range are to be expected in smaller regions where sea level rise estimates do not cover such a large geographic area.

Figure 4. Projected future sea level by NPS region for 2100 under RCP8.5 (the “business as usual” climate change scenario). Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each region.

Based on the averages per region, we found that the shoreline within the National Capital Region is projected to experience the highest sea level rise by 2100 (0.80 m RCP8.5), although this number does not include the full extent of changes in land level over the same time interval. The shoreline near Wright Brothers National Memorial in the Southeast Region has the highest overall projected sea level rise (0.82 m, RCP8.5, 2100). Glacier Bay Preserve and Klondike Gold Rush National
Historical Park are tied for lowest projected sea level rise at 0.33 m using RCP8.5 for 2100. The Alaska Region also has the highest standard deviation among park units. The National Capital Region conversely has very little standard deviation due to the compact nature of the region (meaning that all of the parks units fell within the same raster cell). This is not to say that all of the parks will experience exactly the same rate of sea level rise, but that the IPCC model projected that sea levels could rise up to an average 0.80 m (RCP8.5) for that region by 2100. The sea level rise maps (discussed in the National Capital section below) illustrate differences among the National Capital parks in more detail.

Comparing RCP8.5 data for 2030 and 2050 (Figures 5 and 6, respectively) shows the Northeast Region almost tied with the National Capital Region in 2030 based on average projected sea level rise, with the National Capital Region ranked highest. The Alaska Region ranks lowest for all three time intervals followed by the Pacific Northwest region, Intermountain Region, and Southeast Region. The Northeast Region ranks second highest for 2050 and 2100.

Figure 5. Projected future sea level rise by NPS region for 2030 under RCP8.5 (the “business as usual” climate change scenario). Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each region.
Storm surge was mapped for 79 park units. We list data for one storm category higher than the highest historical storm in Table D3 in Appendix D. Some (31) park units did not have a historical storm path occurrence within 10 miles of their boundaries, so a Saffir-Simpson hurricane 1 was simulated for these locations. The lack of a historical storm does not mean that these parks are not subject to strong storms. It may merely be that these parks are in regions that either do not have extensive historical records or they experience strong storms, such as nor’easters, that behave differently and are not part of the NOAA database.

The Southeast Region has the strongest historical hurricanes (average of highest recorded storm categories = 2.79), followed by the Intermountain Region (average = 2.33), National Capital Region (average = 1.90), and the Northeast (average = 1.03). None of the historical data intersected with the 10-mile (16.1 km) buffers around the Alaska Region parks. The Pacific West Region has experienced some tropical depressions, particularly in Hawaii, but most of their storm surges are driven by other phenomena, such as mid-latitude cyclones or extreme tides (sometimes colloquially referred to as king tides). The strongest (highest winds) and most intense (lowest pressure at landfall) recorded historical storm to have impacted a park unit was the “Labor Day Hurricane” that passed within 10 miles of Everglades National Park in 1935. While this storm may have been the highest intensity storm, it is certainly not the most damaging or costly storm in National Park Service history.
**Northeast Region**

Colonial National Historical Park, Fort Monroe National Monument, and Petersburg National Battlefield have the highest projected sea level rise in 2050 and 2100, and, together with Edgar Allen Poe National Historic Site, Fort McHenry National Monument and Historic Shrine, Independence National Historical Park, and Thaddeus Kosciusko National Memorial (parks near coastlines) they also have the highest projected sea level rise for 2030. However, while these parks may have ranked highly, caution should be used in applying these results. Many of these parks do not have coastline and so these projections are based on sea level rise for the coastline adjacent to these parks. The maps in Appendix A show how the projected sea level rise may affect each of these parks. Colonial National Historical Park, Fort McHenry, and Fort Monroe National Monument are the only park units of this highest rise grouping that contain coastline with their boundaries.

Figure 7 shows the range of sea level projections for the Northeast Region for 2100, averaging between 0.49 m (RCP2.6) and 0.74 m (RCP8.5) of sea level rise by the end of the century. Acadia National Park had the lowest projected rates of sea level rise for 2030 (0.08–0.10 m), 2050 (0.14–0.19 m), and 2100 (0.28–0.54 m).

![Figure 7](image-url)  
**Figure 7.** Projected future sea level rise by 2100 for the NPS Northeast Region under all of the representative concentration pathways. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation of each mean. Blue bars mark the full range of sea level estimates for each category.
Regarding storm surge, the highest recorded storm to have travelled within 10 miles of any of the 29 parks units identified for study was an officially unnamed hurricane in 1869 known colloquially as Saxby’s Gale, which was classified as a Saffir-Simpson 3 hurricane. The storm path passed present-day Boston National Historical Park and Roger Williams National Memorial. Figure 8 shows the estimated extent and height of a storm surge from category 3 hurricane striking Boston Harbor Islands National Recreation Area at mean tide.

**Figure 8.** Estimated storm surge created by Saffir-Simpson category 3 hurricane occurring at high tide near Boston Harbor Islands National Recreation Area. Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range).

**Southeast Region**
Historically, the Southeast Region has the highest intensity storms (highest Saffir-Simpson storm category); Everglades National Park has recorded a category 5 hurricane within 10 miles of its boundary, the colored areas in Figure 9 indicate the potential height and extent of a storm generated by two different categories of hurricane. A category 2 hurricane could completely flood the park.

Future storm surges will be exacerbated by future sea level rise nationwide; this could be especially dangerous for the Southeast Region where they already experience hurricane-strength storms.
Moreover, sea level rise projections only include changes in land movement due to glacial isostatic adjustment and do not include the full range of drivers of potential changes in land level. Using Table D1 from Appendix D as a rough guide, changing land level for parks near tide gauges can be evaluated. For example, the Eugene Island, Louisiana tide gauge’s current rate of sea level rise is the highest in the country at 9.65 mm/y, owing in part to the large rate of subsidence in the region (Figure 1). Using the nearest tide gauge to Jean Lafitte National Historical Park and Preserve (Grand Isle, Louisiana, gauge 8761724) we can estimate that land will subside by 7.60 mm/y. Applying this estimate of subsidence (using a baseline of 1992) to our RCP8.5 projections, the park could experience approximately 0.41 m of relative sea level rise by 2030 followed by 0.69 m by 2050 and 1.50 m by 2100. This is an inexact estimate of the land movement for the park given that Jean Lafitte National Historical Park and Preserve is approximately 60 miles (97 km) from the tide gauge; still, factoring in changes in land level, we can see that relative change in sea level is more than double the projected change in sea level using the IPCC estimates alone.

This analysis projects that, by 2100, the shoreline adjacent to Wright Brothers National Memorial may have the greatest sea level rise among the Southeast Region’s parks (0.82 m RCP8.5). Given elevations within the park, this may not inundate a large area of the memorial, unless combined with other factors such as a storm surge. For example, the park may be almost completely flooded if a category 2 or higher hurricane strikes on top of inundation from sea level rise.

Nearby Cape Hatteras and Cape Lookout National Seashores are projected to experience sea level rise of up to 0.79 m and 0.76 m, respectively (RCP8.5) by 2100, resulting in large areas of inundation. While sea level rise around these national seashores may not be as high as what has been projected for Wright Brothers National Memorial, they serve as examples of how caution must be used when using these numbers to assess which park units are most vulnerable to sea level rise. Other factors, such as percent of exposed land, changes in land movement, and adaptive capacity must also be taken into account for vulnerability analyses (Peek et al. 2015).
Figure 9. SLOSH MOM storm surge maps for a Saffir-Simpson category 1 (left) versus category 2 hurricane striking Everglades National Park at mean tide (right). Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range).
National Capital
National Capital Region has minimal variability in projected sea level rise because all park units selected for study are adjacent to the same section of coastline that was modeled. Their proximity also explains why they share the same storm history. Despite these similarities, projected sea level rise may affect each individual park unit differently based on local topography. The strongest storm recorded within 10 miles (16.1 km) of the National Capital Region parks was a Saffir-Simpson category 2 hurricane that struck the city in 1878. While the 1878 storm caused relatively little damage, we can expect a significantly larger amount of damage if a similar storm struck the city again given considerable development now existing in the area. Figure 10 shows the extent of flooding caused by a Saffir-Simpson category 2 hurricane. A storm surge measuring more than 3 m could travel up the Potomac River causing large amounts of flooding. Such a storm surge could be worse by the end of this century given projected sea level rise around the Capital Region of up to 0.8 m.

Figure 10. A SLOSH MOM map showing storm surge height and extent created by a Saffir-Simpson category 2 hurricane striking the Washington D.C. region at high tide. Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range).
IPCC/SLOSH models showed either storm surge or sea level rise (or some combination of the two) affecting every National Capital Region park included in this analysis, with the exception of Harpers Ferry National Historical Park. Our mapping efforts revealed that Harpers Ferry National Historical Park (located approximately 149 m above sea level) is unlikely to experience any impacts of sea level rise due to its elevation and is unlikely to be damaged by storm surge from a hurricane, given its relatively protected location behind several dams along the Potomac and Shenandoah Rivers.

Sea level rise alone is not expected to spread very far into Washington D.C., although a large section on the east side of Theodore Roosevelt Island could be inundated. However, storm surge flooding on top of this sea level rise would have widespread impacts.

**Intermountain Region**

The Intermountain Region covers mostly inland park units stretching from Texas to Montana. Within the region, only three park units in Texas are subject to sea level change: Big Thicket National Preserve, Palo Alto Battlefield National Historical Park, and Padre Island National Seashore. Of these, Padre Island National Seashore may experience the greatest effects of sea level and storm surge; sea level is projected to rise 0.46–0.69 m (RCP2.6–8.5, Figure 11) by 2100. The same amount of sea level rise is projected for the shoreline near Palo Alto Battlefield National Historical Park, but inundation is not projected to extend far enough to reach the park. Palo Alto Battlefield National Historical Park has no history of being within 10 miles of any hurricane, making the site unlikely to be flooded by storm surge. SLOSH MOM models for the park unit show that the region would have to have either a Saffir-Simpson category 4 hurricane striking at high tide or a category 5 hurricane striking at any tide in order for the park to experience any storm surge. On the other hand, Figure 12 shows that Padre Island National Seashore, located to the east of Palo Alto Battlefield National Historical Park, historically was within 10 miles of a category 4 hurricane. SLOSH MOM data show that should a category 4 hurricane occur here again, it would likely flood almost the entire island.

Storm surge could potentially travel up the Neches River and flood the southernmost part of Big Thicket National Preserve, although both artificial and natural storm surge defenses in Beaumont, Texas, to the south of the preserve, may buffer it from any surge.
Figure 11. Projected future sea level rise by 2100 for the NPS Intermountain Region under all of the representative concentration pathways. Black dots indicate the average sea level rise (m) for all units within the respective regions. Black bars represent the standard deviation from each mean. Blue bars mark the full range of sea level estimates for each category.
Figure 12. A SLOSH MOM map showing storm surge height and extent created by a Saffir-Simpson category 4 hurricane striking the southwestern Texas region at mean tide. The dark green line around the island represents the boundary of Padre Island National Seashore. Colored areas represent areas of flooding. Colors from green to red show estimated height of a storm surge (see inset legend for estimated range).
**Pacific West Region**
The Pacific West Region identified 24 park units for analysis in this study that could be vulnerable to sea level rise and/or storm surge. These units occur over a large area that includes California, Oregon, Washington, Hawaii, American Samoa, and Guam. War in the Pacific National Historical Park in Guam has the highest projected sea level rise at 0.68 m (RCP8.5) by 2100, and shares the highest projected sea level rise with almost all of the Hawaiian park units in 2030 and 2050. The average projected sea level rise range is 0.40–0.58 m (RCP2.6–8.5) by 2100 for the whole region; high standard deviations (0.04 m and 0.08 m for RCP2.6 and RCP8.5, respectively) indicate that park-specific projections vary widely across the region.

At the other end of the spectrum, projected sea level rise around Washington’s Olympic Peninsula and in the San Juan Islands, affecting Ebey’s Landing National Historical Reserve, Olympic National Park, and San Juan Island Historical Park, is expected to occur more slowly, reaching a maximum 0.46 m (RCP8.5) by 2100. This region is subject to tectonic shifts and continuing land movement due to isostatic rebound, further complicating sea level projections. Long-term tide gauge records at Neah Bay, Washington (gauge 9443090), and Tofino, British Columbia, Canada (gauge 822-116), show relative sea levels currently decreasing while tide gauges in Port Angeles, Washington (gauge 9444090), Victoria, Canada (gauge 822-101), and Seattle, Washington (gauge 9447130), show it to be increasing (Zervas 2009). Our projections indicate rising sea level in this region throughout this century, although further investigation of localized changes in land movement could shed more light on this matter.

Park units in the Pacific West Region need to be concerned about potential future storms that could travel along the eastern Pacific Ocean’s increasingly warmer waters. Because of the relative lack of hurricanes in this region historically, we used data from Tebaldi et al. (2012), which includes anomalous surges that could be created by storms, and other factors (very high tides sometimes referred to as king tides). Based on the Tebaldi et al. (2012) data, La Jolla, California (gauge 9410230), has the lowest 100-year storm surge (0.95 m) and Toke Point, Washington (gauge 9440910), has the highest 100-year storm surge (1.96 m) in the Pacific West Region. Tebaldi et al. (2012) did not analyze storm data for Hawaii, Guam, or American Samoa, although IBTrACS (Knapp et al. 2010) does have hurricane records for these areas. Only tropical depressions have been recorded within 10 miles of almost all of the Hawaiian park units we analyzed (Haleakala National Park, Hawaii Volcanoes National Park, Kalaupapa National Historical Park, Kaloko-Honokohau National Historical Park, Puukohola Heiau National Historic Site, and World War II Valor in the Pacific National Monument).

**Alaska Region**
The Alaska Region has the lowest average projected sea level rise (0.28–0.43 m by 2100) compared to the five regions described above. Glacier Bay National Park and Preserve and Klondike Gold Rush National Historical Park in southeastern Alaska share the lowest projected sea level rise (0.33 m, RCP8.5, 2100) while Bering Land Bridge National Preserve on the west coast of the state has the highest projected sea level rise (0.60 m, RCP8.5, 2100).
Figure 1 shows how current relative sea levels vary across the state. Land levels are rapidly rising in the southeast of the region due to isostatic rebound and other tectonic shifts. The net result of these increasing land levels is decreasing relative sea levels for at least the early part of this century. Relative sea level in Skagway, Alaska is decreasing at an average rate of 17.6 mm/y (Zervas 2009). Despite melting ice and other factors outlined in Table 1 that increase ocean water volume, the amount of rising water is insufficient to keep up with land level changes. Seven park units (Glacier Bay National Park, Glacier Bay National Preserve, Katmai National Park, Kenai Fjords National Park, Lake Clark National Park, Sitka National Historical Park) are identified as potentially having decreasing relative sea levels based on the nearest tide gauge data to each of these parks. None of these parks have long-term tide gauges with data spanning at least thirty years. A great strength of using the IPCC (2013) process-based model approach is that, unlike many other semi-empirical models, it does not rely on long-term tide gauge records to statistically project future sea levels. However, sea level projections in this analysis do not include changes in land level. The estimates that we report here represent the expected rise due to water volume expansion alone near to each of these park units. Table D1 shows how land levels are changing at long-term tide gauges across the country. However, given that all of these park units are located far from a tide gauge and that the region is relatively geologically complex, we do not recommend using the land movement numbers from the nearest tide gauge for any of the Alaskan parks.

Storm surge is also very difficult to model for this region. Historically, many of the parks had sea ice along the coastline that helped protect these parks from storm surge. Consequently, NOAA does not have SLOSH MOM models for this region. IBrACS data (Knapp et al. 2010) show a few storm paths that have moved towards the region, but these types of storms typically do not make landfall once they move over colder waters. Alaska does hold the record for the highest intensity (lowest central pressure) storm (Duff 2015). A downgraded super typhoon, Nuri, struck Adak Island, Alaska, in 2014 with recorded winds gusting up to 122 mph. It is impossible to determine an average or peak historical storm surge without adequate tide gauge data.
Discussion

Global mean sea levels have been rising since the last glacial maximum (Lambeck and Chappell 2001, Clark and Mix 2002, Lambeck et al. 2014). Church and White (2006) estimated that twentieth century global sea levels rose at a rate of approximately 1.7 mm/y, although this rate accelerated over the latter part of the century. Comment 7 Slangan et al. (2016) found that emissions of greenhouse gases from human activities have been the primary driver of global sea level change since 1970 and that the rate of sea level rise has increased over time (Table 1). Satellite altimetry data shows that present-day global relative sea levels are increasing at approximately 3.3 mm/y (Cazenave et al. 2014, Fasullo et al. 2016).

The IPCC (2013) projects that, without greenhouse gas emissions reductions, this rate will increase, and that global average sea levels could rise by 0.40–0.63 m (RCP2.6–8.5) by 2100. We used regional sea level projections from the IPCC (2013) generated for 2050 and 2100 in combination with our interpolated projections for 2030 to estimate the amount of sea level rise 118 coastal national park units could experience in the future. Our projections are based on the new representative concentration pathways (Moss et al. 2010, Figure 13), using a process-based model approach.

Figure 13. Radiative forcing for each of the Representative Concentration Pathways (RCPs). An increase in radiative forcing (due to the loading of anthropogenic gases into the atmosphere) will result in higher global average temperatures. RCPs replace the IPCC SRES scenarios. Note how RCP4.5 (yellow line) projections are slightly higher than RCP6.0 (gray line) in the early part of this century. Source: Meinshausen et al. 2011.
Numerous academic articles use mostly semi-empirical models (Rahmstorf 2007) to estimate sea level rise regions across the U.S. The IPCC (2013) lists several semi-empirical sea level rise estimates, all of which result in projections of future sea level that are higher than the IPCC (2013) approach. The differences in these approaches can be attributed to many factors. For example, some of the older papers may have higher sea level estimates because they are based on the older IPCC SRES scenarios (e.g. Vermeer and Rahmstorf 2009, Grinsted et al. 2010, Jevrejeva et al. 2010). Other papers may include input from “expert elicitations” in their sea level projections, in which experts provide their opinion on how much sea level (or a related factor) could rise in the future (e.g. Bamber and Aspinall 2013, Jevrejeva et al. 2014, Horton et al. 2014). Some published articles criticize the IPCC sea level estimates as being too conservative or underestimating rates of future sea level change (e.g. Kerr 2013, Horton et al. 2014). Church et al. (2013) addresses these criticisms by explaining how the IPCC define the probability and likelihood of their estimates, and so they are not discussed in detail here. Recent analyses by Clark et al. (2015) further support the findings of the IPCC.

A key strength of the methods used in this analysis lies in providing a unified approach to identify how sea level change may affect all coastal park units across the National Park System, rather than relying on sea level data generated for specific areas. Our analyses revealed that the National Capital Region is projected to experience the greatest increase in sea level (not taking into account changes in land level). This rise will affect each of the region’s units in different ways depending on the elevation of the individual unit, but it could be significant if combined with a storm surge from a storm such as the Saffir-Simpson category 2 hurricane in 1878.

At the individual park level, IPCC projections reveal the sea level along the coastline adjacent to Wright Brothers National Memorial could rise up 0.82 m (RCP8.5) by 2100, which could lead to significant flooding if the dynamic landforms are not able to keep pace with such high rates of sea level rise. In addition, storm surge impacts at this higher sea level would be significant. The Southeast Region as a whole is generally susceptible to inundation and flooding due to its low-lying nature in many places, particularly in Cape Hatteras and Cape Lookout National Seashores. Our sea level rise maps (Appendix A) highlight how much all of these park units may be affected.

These estimates do not include the latest data on changing land levels. The IPCC included estimates of global isostatic adjustment (Equation 1) in their predictions, but those do not include changes in land level due to other factors, such as earthquakes and groundwater extraction. Comment 9 We expect the latest, state-of-the-art land level estimates to be released by NASA in 2017. In the meantime, we can roughly estimate relative sea level change for a small number of parks based on current rates of subsidence gathered from nearby long-term tide gauge data. We project Jean Lafitte National Historical Park and Preserve to have the greatest relative sea level increase based on the current rate of land movement. Our sea level projections agree with current sea level trends in showing that the southeast Alaska region is experiencing the least amount of sea level rise of anywhere in the National Park System.
Sallenger et al. (2012) discussed how changes in Atlantic Ocean temperatures and salinity (resulting from changes in circulation) could lead to changes in sea level that could create a 1000-km long “hotspot” along the North Atlantic coast from Cape Cod, Massachusetts to Cape Hatteras, North Carolina. We estimate that almost all of the coastal park units in this area would be flooded under these conditions.

It is unknown exactly to what degree future storm surge will affect the Alaskan park units. Accurate long-term (>30 years) storm surge data do not exist for the Alaska region. Even if such data did exist, it would be not be analogous to future conditions in the region because sea ice that had previously protected the shores for many of the western Alaska park units melts to reveal an easily erodible coastline (Frey et al. 2015). The warming of ocean waters in the Gulf of Alaska and Pacific Ocean could also make it more conducive for more storms like Typhoon Nuri to travel north without losing energy as under historic conditions.

The Pacific West Region shows high variability among parks. War in The Pacific National Historical Park in Guam ranks highest in projected sea level rise among units in the Pacific West Region. The large area of the region partly explains the relatively high standard deviation in results for the region. The tectonically complex setting of many of the region’s parks also complicates future sea level estimates. Changes in land movement are somewhat gradual nationwide in comparison to Alaska and the Pacific West Region, especially where earthquakes can rapidly change the position of the land relative to the sea.

Island park units in general are particularly exposed to the impacts of sea level change and storm surge. Many of the barrier island parks, such as Fire Island National Seashore, Assateague Island National Seashore, Palo Alto Battlefield National Historical Park, Gulf Islands National Seashore, and Cape Hatteras National Seashore, are all projected to experience sea level rise of over 0.69 m by 2100 (RCP8.5). This sea level rise, combined with storm surge, could be especially difficult for isolated island park units, such as the Caribbean park units, the National Park of American Samoa, and War in the Pacific National Historical Park, where access to aid in the event of a natural disaster may not be immediately available.
Conclusions

This report presents projections of sea level change (118 parks) and storm surge (79 parks) in coastal park units administered by the National Park Service. Sea level change and storm surge vary geographically, resulting in locally-specific challenges for adaptation and management. It is important to acknowledge that sea level change will affect some parts of Alaska differently than coastal parks in the rest of the country. Northwest Alaska can expect relative sea levels to increase over time; while in southeast Alaska, relative sea levels may continue to decrease over the first part of this century, followed by an increase in relative sea level towards the end of the century.

This project is an important first step in assessing how changes in sea level and storm surge may affect national park units. Using sea level rise and storm surge information, parks can begin to plan for effects on resources, facilities, access, and other areas of management. While methods used here are not appropriate for combining the separate sea level rise and storm surge results, parks should be aware of the potential for synergistic effects of sea level rise and storm surge causing impacts larger than either may cause individually. It is clear that more research can be done on these complex issues to assess how these changes may affect parks and regions. These data can inform future projects related to both natural and cultural resources as well as the planning and management of infrastructure.

Frequently Asked Questions

Q. How were the parks in this project selected?
A. Parks were selected after consultation with regional managers. Regional managers were given a list of parks that authors considered to be vulnerable to sea level change and/or storm surge. This list was vetted by regional managers and their staff who added or subtracted park names based on their knowledge of the region.

Q. Who originally identified which park units should be used in this study?
A. The initial list of parks was approved by the following regional managers: Northeast Region, Amanda Babson (signed 11/27/13); Southeast Region, Shawn Benge (signed 11/14/13); National Capital Region, Perry Wheelock (signed 3/17/14); Intermountain Region, Patrick Malone signed on behalf of Tammy Whittington (signed 11/13/13); Pacific West Region, Jay Goldsmith (signed 11/26/13); Alaska Region, Robert Winfree (signed 11/15/13).

Q. What’s the timeline of this project?
A. This is the culmination of a three-year project that was proposed in February 2012. Initial Fiscal year of funding was 2013.

Q. In what instance did you use data from Tebaldi et al. (2012)?
A. NOAA’s Sea Lake and Overland Surge from Hurricanes (SLOSH) model does not include storm surge predictions for all of the parks used in this study. We used data from Tebaldi et al. (2012) where reasonable to provide data for park units in California, Oregon, Washington, and southern Alaska. The following parks used Tebaldi et al. (2012) data: Cabrillo National Monument, Channel Islands National Park, Ebeys Landing National Historical Reserve, Fort Point National Historic Site, Fort Vancouver National Historic Site, Golden Gate National Recreation Area, Klondike Gold Rush National Historical Park, Lewis and Clark National Historical Park, Olympic National Park, Port Chicago Naval Magazine National Scenic Trail, Point Reyes National Seashore, Redwood National Park, Rosie the Riveter WWII Home Front National Historical Park, San Francisco Maritime National Historical Park, San Juan Island National Historical Park, and Santa Monica Mountains National Recreation Area.

Q. Why don’t all of the parks have storm surge maps?
A. Unfortunately some parks do not have enough data to complete a storm surge map. These were parks that were not modeled by NOAA’s SLOSH MOM model or near any of the tide gauges used by Tebaldi et al. (2012). These parks are: Aniakchak Preserve, Bering Land Bridge National Preserve, Cape Krusenstern National Monument, Glacier Bay National Park and Preserve, Katmai National Park, Kenai Fjords National Park, Lake Clark National Park, Sitka National Historical Park, War in the Pacific National Historical Park, and Wrangell – St. Elias National Park and Preserve.
Q. My park only has storm surge maps covering a few Saffir-Simpson categories. Why is that?
A. Some parks, particularly those in the Northeast Region, were not modeled by NOAA for the full range of Saffir-Simpson storm scenarios. This is because it is considered very unlikely that a Saffir-Simpson category 4 or 5 hurricane would be able to sustain itself into the northern latitudes of that region.

Q. Why are the storm surge maps in NAVD88?
A. That is the default datum for SLOSH data. This was a decision made by NOAA.

Q. What are the effects of NAVD88 on sea level and storm surge projections for some parks?
A. The North American Vertical Datum of 1988 (NAVD88) is a datum that is commonly used in North America to refer to the “elevation” of a location. It uses a fixed value for the height of North America’s mean sea level. While this is a popular datum for mapping, it has the limitation that it is based on the observed mean sea level for a single location: Rimouski, Canada. As you move further away from this location you can expect actual sea level to differ from the mean sea level at Rimouski. For locations such as California this can result in a significant difference between observed mean sea level and NAVD88. Your natural resource or GIS specialist will likely have further information about your specific location. Alternatively you can look up the differences in your region by checking the datum information for your nearest tide gauge station: https://tidesandcurrents.noaa.gov/stations.html?type=Datums

Q. Which sea level change or storm surge scenario would you recommend I use?
A. All parks are different, as are all projects. Your choice of scenario may depend on many different factors including risk tolerance and expected time horizon of the project. The NPS has not yet released any guidance on which climate change scenarios to use for planning. We would recommend you contact the appropriate project lead, natural or cultural resource manager, or someone from the Climate Change Response Program for further guidance depending on your situation.

Q. How accurate are these numbers?
A. The accuracy of these data varies depending on the data source. SLOSH data has +/- 20% accuracy, although this is discussed in greater detail by Glahn et al. (2009). Further information about storm surge data generated by Tebaldi et al. can be found in Tebaldi et al. (2012). IPCC global sea level rise projections range between 0.26 m (RCP2.6 minimum likely range) and 0.82 m (RCP8.5 maximum likely range) by 2100. The standard error of the IPCC is explained in greater detail in the Chapter 13 supplementary material in AR5 (IPCC 2013). An explanation on the horizontal and vertical accuracy of the digital elevation models used for mapping can be found in the metadata that accompanies the map data on www.irma.gov. DEM data were required to have a ≤18.5 cm root mean square error vertical accuracy before they were converted to MHHW. An exception to this was in Alaska where these data were not available.
Q. We have had higher/lower storm surge numbers in the past. Why?
A. The numbers given here are meant to represent a maximum based on a typical storm surge category. As described above, there is likely to be some deviation around that number. Certain periods are also likely to result in higher than average storm surges. For example, periodic changes in regional water temperatures (caused by phenomena such as El Niño and La Niña) will impact water levels that will add to any storm surge. Likewise, changes in the North Atlantic Oscillation and Pacific Decadal Oscillation will also affect ocean conditions. This must be taken into account when using these numbers. All of these factors vary temporally and geographically, so contact your natural resource manager if you are unsure how this could impact your particular park unit.

Q. What other factors should I consider when looking at these numbers?
A. These projections do not include the impact of all man-made structures, such as flood barriers, levees, and dams. They also do not take into account how smaller features, such as dune systems or vegetation changes could impact coastal flooding. There are many meso- and micro-scale factors that need to be taken into account such as differences in topography, the presence/absence of any wetlands etc. It should also be expected that as sea levels change, areas of the shoreline will change accordingly, particularly due to erosion and accretion.

Q. Why don’t you recommend that I add storm surge numbers on top of the sea level change numbers?
A. Higher sea level and permanent inundation will change the way waves propagate within a basin. Sea level change is expected to have a significant impact on the geomorphology of the coastline. Changing water levels will lead to areas of greater erosion in some areas as well as increasing accretion in other places. As sea level changes, the fluid dynamics of a particular region will also change. For example, tidal distance will change as water levels rise, which will alter the spatial extent of a storm surge as well as potentially impacting wave height. This is not something NOAA takes into account in their SLOSH model.

Q. Where can I get more information about the sea level models used in this study?

Q. Where can I get more information about the NOAA SLOSH model?
A. http://www.nhc.noaa.gov/surge/slosh.php

Q. So, based on your maps, can I assume that my location will stay dry in the future?
A. No. As explained above, these numbers are accurate within a certain range. Also, these maps are based on “bathtub” models where water is simulated as rising over a static surface. In reality, your coastline will change in response to storms and other coastal dynamics. These numbers are intended for guidance only.
Q. Why do you use the period 1986–2005 as a baseline for your sea level rise projections?

A. We are following the standard approach used by the IPCC, USACE, and much of the academic literature. If you would like your estimate to start from a specific year you can do one of two things: 1) subtract the observed rate of sea level rise since 1992 for your location, or 2) contact park, region, or Climate Change Response Program staff for assistance. It may be possible to interpolate projections further to estimate the amount of rise the models estimate to have taken place between the baseline and whichever year you choose. We must caution that if you follow option 1 you will be introducing some inaccuracy to sea level projections, especially if you use data from a tide gauge that is not close to your location.

Q. The SLOSH/IPCC projections seem lower/higher than X source I’ve found. Why is that?

A. Projections can vary depending on a number of factors such as choice of model, approach, or the age of the study. We would recommend that you speak to a climate specialist when choosing sources.

Q. What are other impacts from sea level rise that parks should consider?

A. Impacts from sea level rise could include, but are not limited to, increased erosion, damaged cultural resources, damage to above and below ground infrastructure, difficulty accessing inundated infrastructure, increased groundwater intrusion, altered groundwater salinity, diminished space for recreational activities (possibly leading to conflict between different recreational users), and the complete loss or migration of certain coastal ecosystems. For more information on the topic, please see the Coastal Adaptation Strategies Handbook at: http://www.nps.gov/subjects/climatechange/coastalhandbook.htm
Appendix C

Waysides

The following pages show the final designs for waysides that were installed in parks as part of the funding for this project. Gulf Islands National Seashore received two waysides that were received in 2015. Jean Lafitte National Historical Park and Preserve and Fire Island National Seashores waysides were installed in 2016.
See Change...

The earth’s climate is changing, raising sea level and increasing the frequency of storm surges. Erosion and rising sea level change the shape and size of barrier islands and mainland shorelines along the Gulf Coast.

The roots of coastal plants slow erosion by anchoring the land. As sea level rises, increased salt content in the soil will kill the plants leaving the land exposed to more erosion. In many places, the amount of dry land is decreasing at a significant rate.

The Gulf Coast draws millions of visitors to relax in the bright sun, play in the crystal blue surf, explore the snow white beaches, and watch for wildlife. Yet, this dry land, at the edge of rising waters, could be claimed by the Gulf of Mexico forever.

Gulf Islands National Seashore is investing in energy efficient equipment and seeking new sustainable solutions to help keep these shores from disappearing beneath the rising sea.

Each year, erosion, storms, coastal development, and rising sea level shrink the nesting beaches habitat of sea turtles. When a female sea turtle is ready to lay her eggs, she will try to return to the same sandy beach every two to three years. Will her nestling home still be here?

Please join the National Park Service in protecting these beaches, so that you and your children may watch her hatchlings return to lay their eggs.

The road at Fort Pickens gets overwashed with storm waves. As the sea level rises, these events are becoming more common.
See Change...

The earth’s climate is changing, raising sea level and increasing the frequency of storm surges. Erosion and rising sea level change the shape and size of barrier islands and mainland shorelines along the Gulf Coast.

The roots of coastal plants slow erosion by anchoring the land. As sea level rises, increased salt content in the soil will kill the plants, leaving the land exposed to more erosion. In many places, the amount of dry land is decreasing at a significant rate.

The Gulf Coast draws millions of visitors to relax in the bright sun, play in the crystal blue surf, explore historic forts, and watch for wildlife. Yet, this dry land, at the edge of rising waters, could be claimed by the Gulf of Mexico forever.

Gulf Islands National Seashore is investing in energy efficient equipment and seeking new sustainable solutions to help keep these shores from disappearing beneath the rising sea.

Fighting the Rising Sea

Each year, erosion, storms, shipping channels, and rising sea level are changing the shoreline of the barrier islands. The National Park Service and Corps of Engineers work together on restoration projects to rebuild the coastline around historic Fort Massachusetts. The fort is often threatened by waves, putting the structure in jeopardy.

Please join the National Park Service in protecting our resources, so that you and your children may continue to enjoy these historic places.
Sinking Land, Rising Water

This is the Barataria Basin, built of soil washed to this area by the Mississippi River. This soil is still compacting and sinking, a process called subsidence. Most of the Barataria Preserve is less than two feet above sea level, and its subsidence rate is nearly half an inch a year.

Meanwhile, glaciers and polar ice sheets are melting and our warming climate is heating oceans everywhere, making their waters expand just like water does when you heat it on the stove. Everywhere on the planet, the oceans are a little higher every day.

The combination of the Barataria Basin's sinking land and global sea level rise means that the ocean is creeping in faster here than almost anywhere else in North America.

- Floods are becoming more frequent and lasting longer
- Coastal wetlands are disappearing as land sinks and water rises
- Less land is available to buffer Gulf of Mexico storms
- Storm and flooding threats to homes, communities, and infrastructure like highways, ports, and energy facilities are increasing
- Salt water from the Gulf is moving into freshwater wetlands, killing the plants that hold the land together
- Death of plants, animals, and microbes that cannot tolerate increased flooding or salt water
See Change In A Changing Climate

Natural landscape change can be nearly imperceptible on a barrier island, as the wind and waves gradually shape the shoreline, beach, and dunes. Natural changes can also be obvious and happen quickly during storms like hurricanes and nor’easters. Looking ahead, storms will have a greater impact on Fire Island due to climate change.

When we burn fossil fuels, carbon dioxide is released into the atmosphere and acts like a heat trapping blanket around our planet. Heat that would normally escape from the atmosphere is retained, warming the Earth, and changing climate patterns. As ocean waters warm and ice on land melts, sea level rises and impacts Fire Island and coastlines all over the world. The future of this barrier island is in jeopardy due to these human-induced climate change effects.

Fire Island protects mainland Long Island against storms and is a stunning setting for recreation, education, and inspiration. It also provides critical habitat for plants and wildlife. We must do what we can to protect this special place. By using renewable energy sources and reducing our dependence on fossil fuels, we can take steps today to preserve barrier island systems and processes, and help build natural resilience to future storms and sea-level rise.

Storm Stories

On October 29, 2012, Hurricane Sandy struck Fire Island National Seashore and changed the layout of the land. During the storm high water and large waves scour sand from the beach and dunes, moving sand across the width of the island, and carved the breach, pictured here, through the barrier island. The storm was the strongest in recorded history to make landfall in this region.

To learn more about how climate change is impacting the Seashore, please visit www.nps.gov/fiis/learn/climatechange.htm

†Number of years used by the USACE to calculate sea level change (source: [http://www.corpsclimate.us/ccaceslcurves(superseded).cfm](http://www.corpsclimate.us/ccaceslcurves(superseded).cfm))

‡It is not recommended that you use this tide gauge data to determine land level for this park. The boundary is located either too far away or on a different land mass to where the nearest tide gauge is, which increases the inaccuracy of this data. It is strongly recommended that you wait for the forthcoming NASA report on land level (Nerem in prep).

*The park boundary stretches over either large or multiple areas. More than one tide gauge record is appropriate for this park.

NPS 999/137852, May 2017
Comment 1: First Paragraph of Executive Summary (p vii)

Changing: Ongoing changes in relative sea levels and the potential for increasing storm surges present challenges to national park managers. This report summarizes work done by the University of Colorado in partnership with the National Park Service (NPS) to provide sea level rise and storm surge projections to coastal area national parks using information from the United Nations Intergovernmental Panel on Climate Change (IPCC) and storm surge scenarios from National Oceanic and Atmospheric Administration (NOAA) models. This research is the first to analyze IPCC and NOAA projections of sea level and storm surge under climate change for U.S. national parks. Results illustrate potential future inundation and storm surge due to climate change under four greenhouse gas emissions scenarios. In addition to including multiple scenarios, the analysis considers multiple time horizons (2030, 2050 and 2100). This analysis provides sea level rise projections for 118 park units and storm surge projections for 79 of those parks.

Comment 2: Third Paragraph of Executive Summary (p vii)

These results are intended to inform park planning and adaptation strategies for resources managed by the National Park Service. Sea level change and storm surge pose considerable risks to infrastructure, archeological sites, lighthouses, forts, and other historic structures in coastal units of the national park system located along the coast. Understanding projections for continued change can better guide protection of such resources for the benefit of long-term visitor enjoyment and safety. These results are intended to inform park planning and adaptation strategies for resources managed by the National Park Service.

Comment 3: First Paragraph of Introduction (p 1)

Sentence shown in green font hasn’t changed from the draft report. Suggest changing it back to black font. Yellow highlight text is very user-unfriendly; can we fix this at the same time?

Global sea level is rising at an increasing rate. While sea levels have been gradually rising since the last glacial maximum approximately 21,000 years ago (Clark et al. 2009, Lambeck et al. 2014), anthropogenic climate change has significantly increased the rate of global sea level rise (Grinsted et al. 2010, Church and White 2011, Slangen et al. 2016, Fasullo et al. 2016). Continued warming of the atmosphere will cause sea levels to continue to rise, which will have a significant impact on how we protect and manage our public lands. The rate of warming depends on numerous factors considered by the Intergovernmental Panel on Climate Change (IPCC) under four different representative concentration pathways (RCPs; Moss et al. 2010, Meinshausen et al. 2011). Used as the basis for this report, the RCPs are climate change scenarios based on potential greenhouse gas concentration trajectories introduced in the fifth climate change assessment report of the Intergovernmental Panel on Climate Change (IPCC 2013). The IPCC’s process-based approach for estimating future sea levels contrasts with other estimates from semi-empirical techniques that commonly generate higher numbers.

Comment 4: Second Paragraph of Introduction (p 1)

Peek et al. (2018) estimate that the cost of sea level rise in 100 National Park Service units could exceed $23 billion if these units were exposed to one-meter of sea level rise. The aim of this report is to: 1) quantify projections of sea level rise over the next century based on the latest IPCC (2013) models, and 2) show how storm surge generated by hurricanes and extratropical storms could also affect these parks. [report to be cited as In Preparation]

Comment 5: Third Paragraph of Introduction (p 1)

When Hurricane Sandy struck New York City in 2012 it caused an estimated $19 billion in damage to public and private infrastructure (Tollefson 2013). This single storm cannot be attributed to climate change, but the storm surge occurred over a sea whose level had risen due to climate change. Extreme storms such as Hurricane Sandy have extreme costs. When Hurricane Sandy struck it was estimated to have a return period between a 398 year (Lin et al. 2016) and a 1570 year storm (Sweet et al. 2013). Currently, a 100 year storm surge in New York City could cost $2-5 billion and a 500 year storm surge could cost $5-11 billion (Aerts et al. 2013). Under future scenarios of increasing greenhouse gas emissions, models project increasing storm intensities (Mann and Emanuel 2006, Knutson et al. 2010, Lin et al. 2012, Ting et al. 2015).

Comment 6: First Paragraph of Methods >> Sea Level Rise Data (p 4)
Sea level rise is caused by numerous factors. Ice located on land and in the sea melts with the rise of mean global temperatures (IPCC 2013, Gillett et al. 2013, Frolicher et al. 2014). The melting of ice found on land, such as Greenland and Antarctica, is a significant driver of sea level rise.

Comment 7: First Paragraph of Discussion (p 26)
Global mean sea levels have been rising since the last glacial maximum (Lambeck and Chappell 2001, Clark and Mix 2002, Lambeck et al. 2014). Church and White (2006) estimated that twentieth century global sea levels rose at a rate of approximately 1.7 mm/y, although this rate accelerated over the latter part of the century. SLanguan et al. (2016) found that emissions of greenhouse gases have been the primary driver of global sea level change since 1970 and that the rate of sea level rise has increased over time (Table 1). Satellite altimetry data shows that present-day global relative sea levels are increasing at approximately 3.3 mm/y (Cazenave et al. 2014, Fasullo et al. 2016).

Comment 8: Caption of Figure 13 (p 26)
Radiative forcing for each of the Representative Concentration Pathways (RCPs). Positive radiative forcing means Earth receives more incoming energy from sunlight than it radiates to space. This net gain of energy will cause warming, resulting in that can be measured as higher global average temperatures. RCPs replace the IPCC SRES scenarios. Note how RCP4.5 (yellow line) projections are slightly higher than RCP6.0 (gray line) in the early part of this century. Source: Meinshausen et al. 2011. 

Comment 9: Sixth Paragraph of Discussion (p 27)
These estimates do not include the latest data on changing land levels. The IPCC included estimates of global isostatic adjustment (Equation 1) in their predictions, but those do not include changes in land level due to other factors, such as earthquakes and groundwater extraction. We expect the latest, state-of-the-art land level estimates to be released by NASA in 2018.
Cat,

I put the latest version of the Caffrey report here:

Z:\CCRP\Communication\300 - Adaptation\Coastal Adaptation\05 - 2018 SLR & SS Report

When you can, please review the results section per our call this week. Also, please review new comment on page 1 and feel free to edit as needed.

I will try to schedule a call with the report authors ASAP. Rebecca is out at NCTC all next week, so we'll shoot for early the week of Feb. 20.

-L

Rebecca & Patrick,

Cat and I would like to organize a call with all authors to review the report.

I propose we plan to meet via webinar at 2:00 MT on February 21...immediately following our large group call. I'll send a calendar invite shortly.

Rebecca, would you kindly forward the invite to Maria as well...we're hopeful she is willing and able to join.

Thanks,

L

See the "CHH" version of the report, back in the S: drive. Plus there's one comment in the document I want to discuss with you (relates to the document in S: folder called "COMMENT")

On Sat, Feb 10, 2018 at 12:23 PM, Perez, Larry <larry_perez@nps.gov> wrote:
